In fact, the experimenters had designed the study to evaluate problem-solving strategies for people who were unable to lose weight.

When the participants' weight loss leveled off, they entered the second phase of the study, which focused on problem-solving strategies designed to help the couples overcome weight loss obstacles. The couples were taught specific skills for encouraging further reduction and they maintained close mail and telephone contact with counselors. During this ten-week period, the participants lost on the average another six pounds, the researchers report.

The third component of the study examined the couples' weight loss progress over a six month period using the learned problem-solving skills with minimal supervision—an average of one-and-a-half pounds were shed by the reducers.

Finally, at a follow-up check three months after completion of the study, the participants had regained an average of only one-and-a-quarter pounds.

Based on these finding, the researchers suggest that people bring into a weight loss program substantial personal resources for achieving weight loss. "Still, the first pounds are often easiest for dieters to lose," they point out, and this may account for some of the initial loss figures.

But overall, "the minimal intervention strategy appears to be a powerful procedure and for some is the only method necessary to reach an ideal level of body fat," the researchers suggest. And the notion that people are able to accomplish substantial weight loss on their own, at home, using simple techniques, may give them lasting confidence to continue losing and to maintain the loss once achieved, the researchers conclude.

Most of these findings were presented at a recent meeting of the Association for the Advancement of Behavior Therapy.

STANFORD—

"Here I am in this beautiful, golden California. Everyone's happy. I should be happy, but I hate it."

So recently lamented a soured-on-sabbatical wife of an academic at Stanford's Help Center.

"I don't have a job. I don't have any friends. And everyone seems so busy."

A sabbatical has the mystique of being a time of casting off the weight and responsibility of teaching and committee meetings, a time of unfettered thought, a time of adventure and of travel to new lands.

But sabbaticals are not always sunny, and the stresses and strains encountered are sending a notable number of people to Stanford University's Help Center for counseling.

The Help Center was started three years ago to provide a problem-solving, short term counseling service for the University, Medical Center and SLAC communities.

"I have had several people tell me," says Linn Hayes, clinical social worker at the Help Center, "'I went on sabbatical once. It was awful; I'll never do it again.'"

"And so they've ruled out what can be a marvelous experience because it was so horrendous the first time," she says.

Before families embark on a sabbatical, they should sit down together and dispel the fantasies and discuss the realities, say Hayes and Sharon Levin, also a Help Center clinical social worker.

"As much as possible every member of the family should be involved in the planning. Obviously, someone has to make the final choice of where to go, but everyone should have some imput," Hayes says.

"If there is no choice in the place, then there should be a choice in whether or not to go.

"Repeatedly, we've heard complaints from the family members who only reluctantly went along, without thinking out what they were going to do. They get to Oshkosh, Egypt or Boston and there is instant cultural shock. Often, without friends or plans, they just become immobilized."

"The academic going on sabbatical should think through what his or her professional goals are, and if they are realistic," Levin says. "Can three books and five articles be written, and a Nobel Prize-winning piece of research be done in one year or six months?"

Sabbatical and Sabbath are both derived from the ancient Hebrew word for rest, but the modern-day reading seems to be restless, a time of frenetic activity.

-more-

"Many people charge into a sabbatical thinking they're going to set the world on fire," says Hayes. "Then, they get there and the department isn't all it was said to be, or the equipment isn't as good as what they've left behind, or the intellectual chats they've imagined before going just don't materialize."

Most people don't give themselves permission to express any ambivalence about the sabbatical, Levin says.

"I'm here, I must be having a good time." people sternly tell themselves, and quietly reprimand themselves, "I better be having a good time."

"It's a year in one's life," Levin says. "It's not a honeymoon. In a normal year, there are ups and downs. Why shouldn't this be true in a sabbatical, when there are even more adaptations than normal to make?"

Those that do remain true to the etymological meaning of the word "sabbatical" and do regroup and rethink during the year may also encounter a crisis, Hayes says.

"I've had people come back and say, 'Things that bothered me about my job and my teaching position here really crystalized while I was away, and I now realize that I'm quite unhappy.'"

If going there and settling in is a wearing experience, coming home can be just as wrenching, Levin says.

"The family has to leave its new friends, and come home to friends that may have changed in the last year."

There's also the problem of how a family handles being in close quarters and forced shared activities for perhaps the first time.

If the challenge of being emotionally elastic doesn't faze the family, the more mundane matter of finances may, Hayes says.

"It just costs more to go on sabbatical these days. Anywhere. Many people used to go to Europe, but an apartment in Paris for a family costs $2000 a month now. There may not be enough money left over to steal away on those little trips the family had planned, or for those activities counted on to entertain and occupy the family during the time away."

Because of the chilling costs involved, a six-month sabbatical is becoming the only choice for many, Hayes says.

All this is not to discourage people from taking sabbaticals, but to tell them that ups and downs are a natural part of the sabbatical leave, Levin says.

STANFORD—

"An experimental operation" is how doctors describe the recent heart-lung transplant performed at Stanford University Medical Center. However, someone had to decide that it was appropriate to do the experiment.

That someone was Stanford's Medical Committee for the Protection of Human Subjects in Research, and the heart-lung surgery is just one of hundreds of research activities which it has reviewed in the past year.

The committee is the medical sub-panel of Stanford's "institutional review board," a requirement of the Department of Health and Human Services (HHS) for all institutions receiving federal funds for sponsored research involving the use of human subjects.

Its purpose, says chairman Philip A. Berger, M.D., associate professor of psychiatry, is three-fold: to protect the human subject; to facilitate research and make sure potential new treatments are not delayed unnecessarily; and to meet HHS regulations. The committee's overriding principle, says Berger, is that in order for a proposed investigation to be approved, it must present greater potential benefits than risks.

"Not many projects are rejected outright, but many go through a long process of modification by the committee," he notes.

More than half of the 60 to 70 proposals reviewed each month are directly affected by committee action—even if it's just a request for additional information. "It's an unusual proposal that doesn't need *some* modification," says Berger, explaining that this might be in scientific design, subject selection, maintaining confidentiality, or other areas.

"One joy of being on the committee," says Berger, "is getting to know many potential new treatments first. It's very exciting, what goes on here at Stanford. We see proposals of people who have won Nobel prizes for their discoveries."

The studies reviewed by the committee are primarily biomedical, usually involving the administration of drugs, chemical agents or blood products, or the study of samples of bodily fluids or tissues. Many also involve surgery.

There is a procedure for screening out proposals that don't need review, based on certain HHS-specified criteria. But, says Berger, who's been a member for five years and chairman for two, when in doubt the committee reviews. "We err on the conservative side."

According to HHS regulations, the composition of an institutional review board must reflect the diversity of attitudes and expertise inherent in any health-related or academic environment. The medical committee at Stanford includes physicians of various specializations, a nurse, an administrator, a lawyer, a pharmacist, an undergraduate student, a medical student, and a community member not otherwise affiliated with the institution. Appointed by the President of the University, all members receive an orientation packet and presentation when they join the committee.

-more-

Each proposal is sent to a majority of the 15 committee members for individual review, every month. They prepare questions and comments for the investigator, who in turn must respond to their queries. The questioning must be anonymous to be effective, so correspondence is routed through Martha Weitzenberg, administrative coordinator since 1973 (the first year the group became organized).

Meeting the first Tuesday of every month, committee members discuss and vote on the proposals they've reviewed. (Often, an outside expert in the field at question is recruited for consultation.) Majority rule decides.

"But a majority of members usually doesn't vote for a proposal if one member has a serious reservation or objection," says Berger. "By the time it is approved," he continues, "most committee members agree."

When a proposal is rejected, there is an appeal procedure which a researcher may follow. Basically, he may appear before the committee to present his case in person, after which the group re-evaluates its decision.

Every proposal must be reviewed at least once a year, after initial approval. Some are reviewed more often, at the discretion of the committee. For the heart-lung surgery, a stipulation was made that ~~before and~~ after each transplant the committee must receive a report on the particulars of the case. The committee does not want to deny this potentially life-saving procedure to anyone who has no other hope. But if in their review of the cases, the members feel that the risks of the operation are outweighing the benefits, they can withdraw approval at any time.

Berger reminds us that there are two types of benefits to human subjects. A large number of projects, including experimental treatments and diagnostic procedures, are expected to be of direct benefit to the subjects involved. Others, through the information they help gather, are expected to be of benefit to society's future patients. And subjects must be informed as to which kind of benefit is hoped for.

They must also be informed of the risks. Some projects are relatively risk-free, such as taking blood samples to study kidney function. Others, however, especially the testing of new and toxic cancer-fighting drugs, do involve potential risks.

The consent form, a very important part of the research procedure, is also of great concern to the review committee. It is the mechanism by which the committee (under HHS guidelines) ensures that no pertinent information is withheld from research volunteers.

Consent forms must include the purpose of the research, the procedures involved, the risks, the benefits, alternative treatments, a statement that subjects are free to withdraw from the research without prejudicing their medical care, and an invitation to ask questions. It specifies that treatment is available in case of harmful effects, and offers the review committee's phone number as a route for feedback.

When subjects are under legal age or suffer from mental disorders, consent is obtained from family members or other legal guardians. Still, says Berger, the general rule is not to force treatment against a subject's will.

It's important that consent forms be both complete and understandable, explains Berger, and this is where the committee often intervenes. In fact, a change in the consent form is the most frequent modification required, and the committee suggests to most investigators that they provide oral explanations to their subjects as well.

-more-

3-3-3

A prerequisite for project approval is effective communication with subjects. "Some researchers are great," says Berger, "and some are terrible." The committee works very hard with the latter type, to make them more sensitive to subjects' needs. As to be expected, says Berger, the committee is viewed both negatively and positively by investigators.

"I think that the committee is absolutely essential," says Berger, "but that there *are* certain requirements on it that do at times get in the way." For example, a proposal must be submitted to study human tissue that would otherwise be discarded during surgery. Because Stanford is doing more research in recent years, the activitiy of the committee has naturally increased, and such trivial reviews as this are viewed as more cumbersome than ever.

Berger is hopeful, however, that with a new set of regulations to become effective July 27, 1981, greater efficiency will be possible.

Amendments to the existing regulations will essentially exempt from regulatory coverage broad areas of research which present little or no risk of harm. These include educational, behavioral and much social science research—areas generally covered by the behavioral sub-panel of the review committee at Stanford. Also exempt will be research involving the collection or study of existing data, documents, records, pathological specimens or diagnostic specimens, when publicly available or recorded so as not to identify the subjects.

Another new provision will be for "expedited review" of certain minimal-risk proposals, whereby approval may be granted by the chairperson alone, or by a designated committee member. The HHS has a detailed list of research categories which are eligible for expedited review.

After passage of the National Research Act in 1974, institutional review boards were informally required to review all research involving human subjects, conducted by institutions receiving funds from HHS under the Public Health Service Act, regardless of where funding for a particular project was obtained.

Effective in July, the regulations will be applicable only to research conducted or funded directly by HHS. Still, committee review and/or other mechanisms for protecting all human subjects is strongly recommended, and recipients of federal funds for covered research must provide HHS with a statement of the institution's methods for protecting the rights and welfare of all subjects, regardless of source of funding.

STANFORD—

On April 21, three days after the seventy-fifth anniversary of the Great San Francisco Quake of 1906, the University will pretend 'the big one' has come, and at 10 a.m. begin its first earthquake drill.

The imaginary earthquake (a 7.5-magnitude quake on the San Andreas, with the epicenter at Crystal Springs in San Mateo county; the 1906 quake was an 8.3) has been supposed to look for any slip ups in the University's plan to handle this major, unpredictable, but almost inevitable, disaster.

Seventy-five years ago this Saturday, the earth under Stanford shook mightily for about a minute in the early morning. The tower and flying buttresses of Memorial Church toppled; the nearly finished library and gymnasium, Memorial Arch, and brick additions to the museum collapsed.

Two persons were killed: a student in the path of an Encina Hall chimney that crashed through four stories to the basement, and a fireman crushed under the falling great stone smokestack of the powerhouse.

Predictions are that the earth in Northern California will most probably quake violently again relatively soon, and the University, flanked by two great faults, the San Andreas and the Hayward—being only five miles from the San Andreas— has been developing a plan to handle the aftermath of a great quake.

The drill has been organized by the Earthquake Preparedness Committee, which was formed last year at Stanford President Donald Kennedy's request, and is being coordinated with Stanford University Hospital's semi-annual disaster exercise.

This is a test to see if the University knows how to respond to a once-in-a-hundred-years earthquake, says Police Chief Marv Herrington, who is head of the Department of Public Safety and has been working on the earthquake preparedness plan for the last 18 months. Anything less serious and not so widespread could be handled using the routine disaster plans, Herrington says.

The overpasses of the freeways, as well as the bridges to the Peninsula, are expected to collapse in a quake of this magnitude, leaving the campus isolated for 24 to 72 hours. Helicopters to airlift those most seriously injured would probably be the only outside aid available.

With this in mind, the megaearthquake plan is geared to self-sufficiency and a cutting of losses, and to a fast and efficient sizing up of what the damage is and of what needs to be done.

At 10 a.m. on April 21, the emergency operations group, assembled at the police station, will get the word that the earthquake has happened. In the imaginary wrecked world, anywhere from 60 to 100 persons will lie dead; 500 to 1000 injured. Fifteen percent of the campus buildings will have been damaged beyond use, at a cost of approximately $120 million.

Because it would be too disruptive to involve the whole campus in the drill, "disaster" will visibly strike only the student residence, Roble Hall, and the Terman Engineering Building.

Fire alarms will signal that Terman is to be evacuated, and a team will be sent in to search for any laggers.

At Roble Hall, a band of broken and battered students, complete with moulages (graphic makeup molds intended to make the exercise more convincing) will await aid. Diane Conklin, who is recruiting the student volunteers, says she expects that as many as 200 students, felled by the gamut of possible injuries will be scattered thoughout and around Roble Hall—in the showers, the laundry rooms, the rooms, the lounges, on the lawn.

-more-

2-2-2

Meanwhile, directed by the ranking police officer on duty, the various members of the operations group will gather the news filtering in from police armed with walkie-talkies out in the field. The operation's group mission is to determine as soon as possible what resources are left intact, who is injured, which places are dangerous, and to get that information out to the policymakers and those that could provide help.

The command post at the police center will alert the Hospital of the disaster, and triage teams, consisting of a doctor, a nurse, and a person outfitted with a walkie-talkie, will be dispatched posthaste to reconnoiter the situation. The teams will radio back to the Hospital what help is needed and where.

In a great earthquake, roads will most likely be impassible and the usual fleet of ambulances and emergency vehicles may not be available, says Dr. Jan Ehrenwerth, chairman of the disaster committee of the Hospital. So whatever transportation is available will be commandeered, he says.

In the president's office will gather a group intent on drawing up sensible short- and long-term plans of action for the University. The president, the provost, vice-presidents of business and finance, of development and of public affairs, the Dean of Students, legal counsel, and representatives of SLAC and the medical center will confer on the information flooding in—a fairly, but not totally, complete picture of what has happened.

They will be called upon to make decisions as to what should or could be done in the pressing short-term—can supplies be brought in from outside the University? Which buildings are safe and available?—and in the licking-the-wounds long-term—When can the University be reopened? With whom will we replace the disabled or dead faculty and staff?

At the same time, the injured students will be being dispatched to either the Medical Center, Cowell Student Health Center or Children's Hospital at Stanford, which are assumed to be damaged but usable.

The majority of those injured, including those most seriously hurt, will be taken to the Medical Center, where the doctors and nurses partaking in the drill will have either reported to the operating rooms or to the triage area in the first floor lobby near the emergency room.

In short order, they will find the operating and emergency rooms overflowing with the wounded, and no empty beds to be had in any of the units.

For the many wounded streaming in, they will have to scramble to set up a mock operating room and cots away from those utilities usually thought of as necessities, such as water, electricity and oxygen—a scenario most probable in a real disaster.

At the various disaster and decision-making areas on campus and at the Hospital, observers will carefully note what happens, Herrington says, and their reports, along with the accounts of the principals involved, will be scrutinized over the next two to three months. The experience gained in the drill will be used to refine both the University's and the Hospital's plans.

When the big one finally comes, Stanford hopes to be prepared to soften the shock.

STANFORD—

The earthquake drill is no idle exercise. There is a 50-50 chance northern California will experience a major earthquake—magnitude 7 or higher on the Richter scale—within the next decade, predict Profs. James Gere and Haresh Shah, codirectors of the John H. Blume Earthquake Engineering Center at Stanford, and Prof. Richard H. Jahns, former dean of the School of Earth Sciences.

And if the great quake doesn't come in the next decade, there is a 75 percent chance that one will occur in the decade after that, says Gere.

Even if the next big quake is not as powerful as the 1906 quake (which was a magnitude of 8.25 on the Richter scale), the damage and death toll is likely to be much higher just because ten times the number of people live in the San Francisco Bay area now.

When a great quake does come, the probability is that you'll be hit by a falling bookcase, rather than a flying buttress.

"We think the possibility is remote that any campus buildings will collapse," says Gere. "but even if the building meets code, the possibility cannot be ruled out.

"On campus, the greatest danger will be from falling ceilings and fixtures and broken glass, overturned file cabinets, and the like.

"In 1978, an earthquake shook the UC Santa Barbara campus on a Sunday afternoon. In example after example, bookcases and file cabinets were found toppled right where people would have been working if it had been a weekday."

It wouldn't take much effort or expense to secure bookcases, heavy furniture, or equipment likely to topple, says Gere, and it would reduce injuries and minimize property damage.

"People should take responsibility for their own safety if they are working or living in an earthquake region." says Gere.

To help them do that, Gere and Shah have prepared a pamphlet, *Earthquakes—How to Protect Your Life and Property.* It details how to prepare for, and what to do during and after the next earthquake.

In preparation for the quake, besides securing the heavy furniture, the water heater and the gas furnace, they recommend that your home be stocked with emergency provisions of food and water, a bedside flashlight, a battery-operated radio, and fire extinguishers. It's unwise to have your bed near a large glass window, they say. And you should know the fundamentals of first aid and the telephone numbers for emergency services.

-more-

During the quake, they advise, above all, to remain calm. Then, if you are indoors, to quickly scurry under a desk, table or workbench, or if no cubbyhole is near at hand, to stand in an interior doorway or in the corner of a room. The idea is to get clear of the path of falling debris, the greatest danger. Running outside is not wise.

But if you are outdoors, head for an open space, away from buildings and power lines, they counsel. If you are in a moving automobile, calmly stop the car away from tall buildings, overpasses and bridges, and stay in it until the shaking stops.

After the quake, the number one thing to do, Gere and Shaw say, is to remain calm (or supposedly to get calm, if you did not prove to be unflappable during the quake.) Then try to help anyone who is hurt or anywhere it is needed.

Caution becomes the order of the day, they say, because buildings could still collapse and explosions could still happen from gas leaks. The danger of substantial aftershocks is always there too.

Gere and Shah's pamphlet was distributed to University employees last fall. Recently, the University's Department of Public Safety has written a brochure, *Earthquake—A Guide for Stanford University Residences,* which includes a campus map that indicates places where students should gather following an earthquake.

Besides the earthquake drill and attempts to educate people on what to do before, during and after an earthquake, the University is heeding its own experts' warnings that a major earthquake may be too soon here. Last year, it purchased a $60 million earthquake insurance policy to cover the loss of buildings and their contents. With a $3 million deductible, the policy's annual premium is approximately $480,000.

In 1979 three Stanford engineering students estimated that damage resulting from a major earthquake to buildings alone, to say nothing of their contents, would cost the University a minimum of $36 million, a maximum of $72 million. If the estimates are in the right range, the policy is well worth the cost.

STANFORD—

Delightful, delicious and deadly is how one doctor describes the wild mushroooms growing in abundance this damp spring.

A recent case of mushroom poisoning at Stanford University Hospital should serve as a warning to those venturing in pursuit of the fungal delicacies in verdant springtime fields, says a clinical associate professor of medicine at Stanford University School of Medicine.

Mushrooms now surfacing in damp soil may look beautiful, says Dr. Lawrence Paaso, a gastroenterologist at the Palo Alto Medical Foundation, but they are extremely dangerous. "If you eat more than two of the most poisonous varieties, your probability of dying is 60 to 70 percent," he says.

The young man recently poisoned has a good chance of pulling through, although he was at one point listed in serious but guarded condition, "a classical case of mushroom poisoning," says Paaso. He may have sampled the most deadly type of mushroom, *Amanita phalloides*, commonly known as "death cap" or "destroying angel," Paaso notes. It grows widely throughout the San Francisco peninsula during fall, winter and spring months.

Victims of mushroom poisoning most likely will feel fine for a few hours and then, six to 12 hours after ingestion, they will suffer from weakness, nausea, and extreme vomiting and diarrhea. Later they may show signs of liver, kidney and central nervous system damage, sometimes with life threatening results.

Treatment consists of close observation and supportive care measures, particularly for the liver and kidney, says Paaso. Unfortunately, "there is no magic antidote available," he adds.

For this reason Paaso urges extreme caution when it comes to harvesting wild mushrooms. Mycologists and other experts at mushroom identification have been known to make mistakes, he cautions, and amateurs expose themselves to great risk when plucking and sauteeing the wild fungi. Harmless varieties of mushrooms often can be distinguished from the more dangerous ones only with great difficulty.

The safest way to savor the flavor of mushrooms is to purchase cultivated varieties from a grocery store, Paaso suggests.

STANFORD—

Nancy Madsen, R.N., associate director for nursing services at Stanford University Hospital, has been appointed assistant Hospital director by Dr. Peter Levin, executive director.

Madsen, who has been the nursing department associate director since joining the Hospital staff in 1978, has held responsibility for the assistant nursing directors and for the day-to-day operations in nursing units throughout the Hospital. Her promotion reflects the increased involvement Madsen has taken in administrative management of the nursing department and her greater role in the management team of the Hospital, according to Levin.

In addition to taking a larger role in overall Hospital management tasks, Madsen has assumed responsibility for nursing recruitment. She has also initiated and carried out several innovative programs within the department.

One such project involves a new classification system of patient acuity that will enhance the department's ability to predict Hospital nurse staffing needs at any given moment. Three times a day, Madsen explains, nurses on each unit evaluate patient conditions in order to determine precisely the unit's staffing needs for the following shift. This system shows promise in improving department productivity, she says. A computerized system currently being installed to automatically process the patient condition information into staffing volume will make the procedure yet more efficient, she adds.

Along with Duane Walker, director of Nursing Services, Madsen has carried out a nursing job satisfaction survey, only the second of its kind within the department. "We are putting into effect some changes that will improve problems identified through the survey," she notes.

Madsen also serves as a preceptor in the department's administrative residency program for graduate nursing administration students from the University of California.

Madsen will continue to report to Duane Walker, R.N., director of Nursing Services and Hospital associate administrator.

Madsen holds an M.S. in nursing from the University of Utah. She came to Stanford in 1978 from Utah, where she held a joint appointment as an instructor in the College of Nursing and as assistant director of nursing service at the University of Utah Health Science Center.

Madsen is a member of numerous nursing professional associations and has been active in nursing research and in consultation to many state and national nursing organizations.

STANFORD—

Deborah Barker has been teased a lot lately. Her friends think she's about to drop everything here, and move on to the big-time in Hollywood.

But Barker says it's not likely. A services representative in Stanford's Hematology clinic since last December, she feels her recent filmed performance on a Perry Como television special was "just one of those things that happen."

Not to everyone. But half-Japanese Barker has a special talent. She plays the koto, a six-foot long, Japanese string instrument, made of native Japanese wood, with 13 strings held up by movable bridges. "It's sort of like a harp," she says.

Barker was spotted by a talent agent during a recent performance in San Francisco, and was asked to film a recital in the Japanese Tea Garden of Golden Gate Park.

The show on which she will appear, to be aired May 10, is Perry Como's Spring in San Francisco Mothers' Day special. And Barker's recital is one of many segments for the program. "I also filled in as the assistant in a magic act," she notes.

It was Barker's first time on television, and it was "kind of fun," she says. "But the make-up artists really went overboard. It's not going to look like me at all!"

Born and raised in nearby Atherton, Barker recently spent a year in Japan, studying the koto, the language, and other aspects of the country's culture and art—the tea ceremony and Japanese pottery, for example.

Although the koto is more popular in Japan than elsewhere, she says, even there it is much less common than such western instruments as the violin, the guitar and the piano.

Barker has played the koto for 14 years, and she's still taking (as well as giving) lessons. Her Japanese mother used to play the instrument. "And I guess it was her dream that her daughters would also play the koto."

So last year, while they were in Japan, both Barker and her younger sister earned the highest degree for koto. "It's sort of like a Ph.D. in koto," she explains.

Barker also holds a B.S. in physiological psychology from U.C. Davis.

She currently belongs to a group of about 60 koto players, which gives regular performances throughout the year. Besides giving its own annual New Year's recital, the group performs at the Cherry Blossom Festival held twice a year in San Francisco's Japanese Trade Center.

EDITORS: The following release announces the Eighth Annual Spina Bifida Association Conference to be held at Fairchild Auditorium, Stanford University School of Medicine and at the San Jose Hyatt House, May 13-15. The conference is in two parts—one for medical professionals, the other for children and adults with spina bifida, their family members, and the general public. Reporters are cordially invited to attend the medical update session, the workshops or the social events. This marks the first time this major spina bifida meeting will be held on the west coast. Media inquiries and arrangements should be coordinated through Gretchen Hecht at the Children's Hospital at Stanford, phone 327-4800, extension 345.

STANFORD—

Spina bifida: it's the second most common neuromuscular birth defect, seven times more frequent than muscular dystrophy and five times more frequent than multiple sclerosis. Yet, most people know little about spina bifida because, until recently, many children born with the defect died soon after birth. At a national conference May 13-15 at Stanford University and at the San Jose Hyatt House, medical professionals, people with spina bifida, their parents and other family members, will gather to discuss recent advances in medical care and in social awareness that have dramatically increased life expectancy and quality of life for spina bifida persons.

The eighth annual conference in a series presented by the Spina Bifida Association of America, it is the first time the meeting is located on the west coast. The theme of the conference is "independence for all," and medical professionals, parents and persons with spina bifida will participate in a joint mission to learn more about spina bifida and to inform the community on how it can help people with spina bifida become more independent.

There are different types of spina bifida with varying degrees of severity. Some are asymptomatic but most individuals develop multiple handicaps. People with spina bifida need medical care from many different specialists for the various complications which accompany the condition. Pediatricians, neurologists, neurosurgeons, urologists, orthopedists, nurses, social workers, physical therapists and orthotists (rehabilitation engineers who custom-design braces and other aids to enhance the patient's mobility and functioning) are all likely to participate in a spina bifida person's care.

-more-

Experts and representatives of these disciplines will present a daylong "medical update" session on Wednesday, May 13 at Fairchild Auditorium at Stanford University School of Medicine. They will discuss the medical and surgical advances that have significantly reduced the high mortality rate that existed just a few decades ago among people with spina bifida. Also on the program are speakers who will address the areas of social and rehabilitation services—and advances in these realms, such as the trend towards improving life for physically handicapped individuals (better facilities, transportation, more aggressive hiring) and how spina bifida children are being mainstreamed into regular schools.

Exhibits and workshop sessions at the San Jose Hyatt House on Thursday and Friday, May 14 and 15, will approach a spectrum of practical living problems that people with spina bifida and their families are likely to face; education for the handicapped, disability and sexual image, legal rights for the disabled, bowel and bladder management, job training, car/van conversion, mobility and orthotic devices, travel and sports.

A number of social and fun events have been planned for the many spina bifida families expected to attend; a barbeque and game room are among the highlights and Marine World and Great America tours are also being offered.

Spina bifida is a defect of neural tube development that begins at one month of age in the unborn child. During normal development, the neural tube is an open structure; gradually it closes—with fusion usually complete by one month into pregnancy—and out of the closed tube emerge the central nervous system components, brain, spinal cord and nerves. Defective fusion of the neural tube along the spine is spina bifida, which actually means "open spine;" the condition afflicts one out of approximately every 600 babies born in the United States.

The higher the lesion on the spinal cord, the greater the resultant muscular paralysis and sensory loss; many remain completely paralyzed from the waist down, and almost all have bowel and bladder incontinence. About 60 percent of spina bifida patients have an associated problem, hydrocephalus, an accumulation of cerebrospinal fluid in the ventricles of the brain. (This condition can be alleviated by threading an artificial tube under the skin, leading from the brain into the abdominal cavity where the fluid may be reabsorbed.)

The conference is hosted by the Spina Bifida Association at Stanford and is co-sponsored by the Spina Bifida Center of the Department of Pediatrics at Stanford Medical School. Continuing medical education credit is available for physicians and other medical professionals who attend.

For further information or to register, call (408) 578-7375.

STANFORD—

Two Stanford psychiatry professors will discuss changing family roles and children and television during a panel discussion on Social Influences in Childhood at 8 p.m., Thursday May 7 in Fairchild Auditorium, Stanford University School of Medicine.

The lectures, open to the public without charge, are sponsored by the Friends of Psychiatry and Behavioral Sciences.

Dr. P. Herbert Leiderman will initiate the program with a presentation on changing family roles. Leiderman has been studying early child care for over a decade. Based on studies conducted in a Kikuyu community outside Nairobi, Kenya, Leiderman has found that, particularly in lower economic groups, multiple caretaking by brothers, sisters, other relatives and friends as well as by the mother, enhanced childrens' learning abilities.

Dr. Alberta Siegel will address the influence of television on children. Siegel has conducted research on the topic of mass media violence and its effects on children for over 20 years and has written numerous articles on this and related subjects. She was also a member of the U.S. Surgeon General's Scientific Advisory Committee on Television and Social Behavior from 1969 to 1971.

Moderator for the program will be Dr. Thomas Anders, head of the division of child psychiatry and child development at Stanford Medical School. Dr. Thomas Gonda, chairman of the Department of Psychiatry and Behavioral Sciences, will present the speakers.

For further information call the Friends of Psychiatry at (415) 497-6376.

STANFORD—

Registered nurses from Stanford University Hospital will express their opposition to lowering the passing scores on California nursing Board examinations Friday April 24 at a public meeting of the California State Board of Registered Nursing (BRN).

The hearings will take place in San Francisco at 9 a.m. in the auditorium of the State building at 450 Golden Gate Avenue.

According to Claire Mailhot, R.N., chairperson of the legislative committee in Stanford Hospital's Nursing Department, the BRN is being pressured to reduce examination standards for nurses seeking registration in California in response to a suit filed against the BRN by the Foreign Nurse Defense Fund Group

The suit claims that current exams administered by the BRN are biased and that the passing standards discriminate against foreign and other minority nurses seeking licensure in California, Mailhot says.

Present standards call for scores of at least 350 out of 700 on each of several exams covering a broad range of topics, including pediatrics, obstetrics, psychiatry, medicine and surgery, Mailhot explains. As a result of the suit, the BRN is considering developing new examinations and lowering the passing scores by 100 points or more to a range of 200 to 250, she adds.

"As nurses, our concern is that if nursing examination standards are dropped in California, the quality of nursing care will decline, " Mailhot says.

In addition, if the California BRN decides to redesign the Board exams, as has been proposed in response to the suit, says Mailhot, they will no longer be recognized by other states. This could affect nationwide nurse recruitment efforts carried out by some California hospitals, according to Nancy Madsen, R.N., associate director of Nursing Services at Stanford Hospital.

"We do a lot of nurse recruitment from outside the state," Madsen explains. "If nurses who are already registered in other states have to take an entirely new set of board exams in order to practice as R.N.'s in California, it will make recruitment much more difficult," Madsen says.

It's a reciprocal problem, Madsen adds, since nurses who have been registered in California will not automatically be able to transfer their licensure to other states, as they have in the past.

The BRN is also considering extending interim permits granted to unregistered nurses who have not yet passed the Board exams, Mailhot says.

According to Joanna Nelson, R.N., president of the Committee for Recognition of Nursing Achievements (CRONA), the bargaining unit for staff nurses at Stanford Hospital, this action would allow people who have failed the Board exams to practice as nurses for as long as two years without passing.

Nelson adds that the California Nursing Association (CNA) is opposed to the BRN actions, and the CNA has called a press conference for Friday morning to coincide with the BRN public meeting.

"We have struggled for many years to develop some autonomy for nurses and to gain respect for the nursing profession," says Mailhot. "We are no longer handmaidens—nurses today are required to have a knowledge base that permits us to actively participate and intervene effectively in patient care decisions."

A nationwide nursing shortage has left many hospitals searching for qualified nursing help. But Mailhot contends that lowering professional standards to allow more to enter the nursing ranks is not a promising solution.

"Anyone who thinks this will solve the nursing shortage problem is wrong," she says. "If the quality of nursing is dropped, we'll be pushed back 50 years and many nurses themselves will drop out of the profession," Mailhot predicts.

The Board of Registerd Nursing is a politically appointed body that oversees nursing in the state of California.

STANFORD—

Stanford University Hospital is taking the temperature of its food!

Every day, at both the main center and Hoover Pavilion, the Department of Dietetics monitors the temperature of patient meals.

And three or four times each month, it conducts a "tray assessment," designed to help evaluate the food's quality, quantity and appearance.

The procedure is quite clever. First, a schedule must be arranged—with a selection of Hospital unit, date, meal and time of day. Then, on the specified day, an order is put in for an unoccupied room, by a fictitious name.

Those conducting the assessment wait eagerly in the room for tray delivery. Once it's there, they begin to fill out a special form, covering such items as food appearance ("appetizing," "color-coordinated," "crisp,"...), food texture, neatness of tray, taste and aroma, and portion sizes. They note the time of departure from the kitchen and arrival in the patient room.

"This helps us pinpoint problems sometimes," says Jane Woeckener, R.D., M.S., assistant director of Dietetics/Nutritional Services. She explains that although transit time does vary among units (depending on how far they are from the kitchen), the trip should never take more than 10 minutes.

According to Woeckener, tray assessments—in operation for two years at Stanford—can involve as many as five participants at a time.

"We have representatives from food production, the trayline, clinical dietetics, and more. Different people are involved all the time, both managers and employees, supplying us with feedback from many perspectives. And we assess all meals—breakfast, lunch and dinner—on many different units."

Food temperature, taken both on the trayline in the kitchen and at mealtime in the patient's room, constitutes an important feature of the assessment. Temperature standards, which of course vary among items, reflect ideal heat at serving time.

And the temperature of food containers is taken too, to determine how well dishes have held heat. "All hot menu items are served in insulated and covered dishware," says Woeckener.

To complete the assessment, all participants sign the form, indicating a consensus of opinion. The menu is attached to the form, which is later discussed at both supervisors' and managers' meetings in the Department of Dietetics. Any recommendations for change are implemented as soon as possible.

"The tray assessment system has proven very effective," says Woeckener. Both food and trays have been made more attractive, with everything now at an acceptable height for eating in bed (some items used to be placed too high).

And the hope, of course, is that food quality, above all, has improved. Noted one patient recently on a Community Relations questionnaire, "Nutritious, tasty food with variety." Surely though, comments like "rubbery vegetables" also appear, serving to keep those tray assessors in full swing and on their toes!

STANFORD—

A world-renowned diagnostic radiologist, Dr. Herbert L. Abrams, of Harvard University will deliver the second annual Etta Kalin Moskowitz Memorial Lecture on Thursday, May 7 at Stanford University School of Medicine.

Abrams, the Philip H. Cook Professor and chairman of radiology at Harvard, will discuss "New Imaging Technologies in Oncology: Problems in the Evaluation Process" at 5 p.m. in room M114 of the Medical Center. The lecture is open to the public.

He will also speak on Friday, May 8 at noon in room S092 of the Medical Center on "The Prognostic and Pathologic Implications of Coronary Arteriography."

Abrams, whose special interest is in cardiovascular radiology, is spending this academic year at Stanford on sabbatical, as a visiting professor of radiology and also as a fellow at Stanford's Center for Advanced Study in the Behavioral Sciences.

He was head of Stanford's division of diagnostic roentgenology from 1961 to 1967, before going to Harvard.

Abrams received his M.D. from the State University of New York-Downstate Medical Center in 1946. After residencies in medicine at New York's Montefiore Hospital and in radiology at Stanford University Hospital, he joined the Stanford faculty in 1951 as an instructor in radiology. He became a full professor in 1962. He has published more than 150 scientific articles.

The Moskowitz Memorial Lecture, the first endowed lectureship in the department of radiology, was established through a gift of the Late Etta Kalin Moskowitz. She was particularly interested in advancing those aspects of diagnostic radiology dealing with cancer.

A native of New York City, Mrs. Moskowitz traveled to the West in the early '30's with her husband, Dr. Simon L. Moskowitz, who set up a general medical practice in Brigham City, Utah, in 1935.

A leader in her community's civic and educational organizations, she was particularly interested in health affairs and was active in her county's and state's medical auxiliaries. Mrs. Moskowitz organized her county's mental health agency and was a founding member of her county's Red Cross and American Cancer Society programs.

In the early '60's, following a successful battle against breast cancer, Mrs. Moskowitz focused her interests on fund raising and public education in cancer treatment and research. She established the lectureship shortly before her death in 1978.

STANFORD—

The Hospital's renovated neonatal intensive care unit will be dedicated on Friday, May 1 at a morning symposium.

The three lectures will be given in room M016 in the Medical School from 8 to 10 a.m. Everyone is welcome.

Dr. Robert Alway, retired medical director of the Hospital and former dean of the Medical School, will speak on "Foresight and Hindsight."

"Dedication of A New Neonatal Intensive Care Unit" will be the subject of the talk by Dr. Norman Kretchmer, director of the National Institute of Child Health and Human Development.

Finally, Dr. John Johnson, associate professor of pediatrics at the University of New Mexico and former director of the nurseries at Stanford, will lecture on "Bilirubin Metabolism."

After more than four years of planning and one and a half years of construction, babies were moved in the expanded and renovated unit on April 14.

NOTE TO EDITORS: The bright-hued, neonatal intensive care unit of Stanford University Hospital, renovated at a cost of more than a million dollars, was formally dedicated on May 1. After more than four years of planning and one and a half years of construction, the unit, which was pinched for space, is now spacious and airy.

Orange and yellow cats and dogs populate the curtains, and the walls-of-drawers are lollipop-colored orange, yellow or blue. The space for each of the unit's 25 beds has been enlarged from 25 to 100 square feet and a number of new facilities have been added: a conference room for physicians and nursing staff, a treatment room, a parents' room in which a baby can be breast-fed, a house staff sleeping room, and a clean and dirty utility room.

More than 800 critically-ill infants are admitted annually to the unit from throughout the Western states. They range from the three-months premature babies, who have a multitude of problems, to the full-term babies suffering from pneumonia or genetic diseases.

The unit outgrew its old surroundings because of the immense influx of high technology into newborn intensive care during the last ten years. Babies no longer just need incubators, but also banks of green screens with blipping lights to monitor their vital functions.

"There has been a technological revolution in medicine, and a tremendous application of technology has come in the area of newborn intensive care," says Dr. David Stevenson, associate director of the unit.

With the advent of the technology has come the ability to save babies once thought hopeless. Following are two stories, one about the problems facing the premature infants, the other about the challenges facing their families.

Treating Premature Infants: How Far Have We Come

A pint-sized stuffed koala bear hugs the transparent tubes threading through the hole in the plexiglas side of Jason's enclosed bed. Jason almost looks transparent too, his pellucid skin with its texture of fine vellum maps his small veins and arteries.

Tiny, soft chicks and orange bugs with black tossles for eyes also share Jason's bed, but Jason's eyes are closed, and you suspect he doesn't notice.

Jason, who was born two months ago weighing only one pound and nine and a half ounces, sucks at the tube which snakes to his mouth bringing oxygen for his little lungs.

Jason is lucky; if he had been born five years ago, chances are he would have died.

But today, approximately 75 per cent of the babies born weighing only between 750 and 1000 grams (1.6 to 2.2 pounds) who are in Stanford University Hospital's intensive care nursery will live, says Dr. David Stevenson, associate director of the unit.

"There has been a technological revolution in medicine, and a tremendous application of technology has come in the area of newborn intensive care," he says.

"We're now treating twenty-five or thirty of those babies a year, and every year the number is increasing. Ten years ago we would only save one or two a year.

"And information gathered over the last 20 years—even before we've had the kind of survival rate achieved over the past three years— leads us to believe that most of the babies in this very low birth-weight group go on to be normal.

-more-

"That's what makes what we are doing worthwhile. If we were producing a large number of incapacitated people, it wouldn't make much sense to be doing this kind of work."

On Jason's chest are taped wires which wend their way to electronic monitors surrounding his bed. They continually check his heart rate, breathing pattern and blood pressure; other wires make sure he maintains the right temperature. His blood gases are monitored continuously to check that he's not getting too much oxygen, which could blind him.

Even with the new technology, a too-soon baby has a long uphill fight, and often has a galaxy of problems to overcome.

A beeping starts on the other side of the large room, which is the central part of Stanford University Hospital's expanded and renovated new-baby intensive care unit. A nurse rushes over to the baby in trouble and gently prods his foot. He begins breathing again, and the beeper stops.

The momentary stopping of breathing by a preemie is not a rare occurence. Probably 30 per cent of the preemies will suffer from apnea, or intermittent cessation of breathing, at some time during their stay in the intensive care unit, says Dr. Ronald Ariagno, associate director of the unit.

Dr. Anneliese Korner, an adjunct professor at Stanford, found that infants placed on oscillating water beds had significantly fewer apneas than did infants in standard incubators, presumably because of the movement. One type of waterbed used allows the baby to experience the rocking produced by his own movements; another provides in addition to the baby's own waves, gentle, irregular oscillations in the rhythm of the mother's respirations.

The lungs develop more slowly than any of the body's other systems, only maturing shortly before the usual time of birth: 38 to 42 weeks after conception. Babies born before their time arrive in the world lacking an essential lung chemical, called surfactant (a surface-active agent), that is necessary to keep the small sacs in the lungs from collapsing every time the babies exhale.

Those babies without surfactant develop respiratory distress syndrome (RDS), a disease that killed most of them only ten or fifteen years ago. But ventilators in the last decade or so have now been refined to deliver air to the fragile, developing lungs in a more gentle manner, and doctors have learned through experience when and how they should help the baby breathe.

"When I came to Stanford in 1959," says Dr. Philip Sunshine, director of the unit, "We didn't even understand how we should wean the baby off the respirator once we put him on it. We've come a long way in helping babies with lung problems."

Besides refining the technology, doctors discovered that if a woman's premature labor can be stopped for a few days and she is given a steroid hormone, such as betamethasone, her baby will have developed some lung surfactant by the time of birth, says Stevenson. But, he adds, the drugs used to stop premature labor and mature lung function are still considered to be investigational, and their use entails some risks.

Interestingly, giving the steroid beta-methasone 24 to 48 hours before premature delivery decreases RDS in female, but not male, infants. Stevenson says the reasons for the difference are not clear, but adds,

"In general, pemature baby girls do much better than premature baby boys. Overall, if you are going to be premature, you'd prefer to be a little girl."

Babies who have been born after developing as few as 26 weeks are now being saved, Stevenson says. But the technology being used to help these three-month early babies breathe won't be able to help those any less mature, he says.

The lungs of babies younger than 26-weeks gestation are so undeveloped that even if oxygen is pushed down into them, blood vessels have not yet grown close enough to the small air sacs for the oxygen to be picked up and carried to where it is needed in the brain, heart and other organs.

Poorly-functioning lungs are often the most immediate threat to the premature or sick baby. Pneumonia, and air-block syndromes can also strike.

-more-

3-3-3 Although the cause is still uncertain, sudden infant death syndrome (SIDS), sometimes called "crib death," may also be a result of breathing difficulties. An apparently well infant in his first year of life will unexpectantly and unexplainably die.

Dr. Ariagno, working with members of Stanford's Sleep Disorders Center, has been trying to better understand the causes of apnea, and how it is related to sudden infant death syndrome.

"One idea is that the difficulty an apnea baby might have is some trouble with awakening," Ariagno says.

Apnea occurs most often during sleep.

The baby may not be able to wake up when he meets a challenge that his sluggish, sleeping body cannot adequately respond to, he says.

"There is insufficient data to say that this inability to change from a sleep to a waking state is truly important, but some preliminary data suggest that this is an important area of adaptation that doesn't function well in babies that have apnea."

Sudden infant death syndrome strikes one to three babies out of every thousand born, Ariagno says. In some reports, babies who are graduates of intensive care units seem to be at a highter risk: as many as 44 out of every thousand will develop SIDS after they've gone home apparently well, he says. But this has not proved to be the case at Stanford, he says.

Ariagno and his colleagues are trying to identify those things that make an infant prone to apnea, such as what it is about brain injury that predisposes a baby to stop breathing.

Babies are rarely dying from lung disease any more, Stevenson says, at least in those cases where ventilators can help.

"Now, we are confronted with babies with many other problems, especially metabolic and nutritional ones," he says. "And the only way out of their tenuous situation is to grow."

But feeding can be a major problem with prematurely born infants, who do not absorb milk sugars well. Dr. Sunshine has found that preemies don't have enough of an intestinal enzyme needed to break down the sugar in milk, lactose, and so don't digest milk well.

Lacking the strength to suck at breast or bottle, and having immature swallowing mechanisms that may cause choking, gagging or breathing of liquids, they sometimes must be fed through a tube threaded down into the stomach, or through their veins.

A primary interest of Stanford's unit has been its reseach into the nutritional problems faced by the premature infant.

"We're aiming at getting sick preemies to become normal people," says Stevenson. "And our biggest concerns are with metabolic stability and improved nutrition."

"Only at 34 or 35 weeks of gestation is the intestinal tract ready for extrauterine life," Dr. Sunshine says. "Before that there are lots of problems."

Dr. Sunshine and Dr. John Kerner, an assisstant professor of pediatrics, have been developing ways to make sure that the baby who must be fed intravenously gets adequate nutrition, but at the same time isn't overloaded with sugars and amino acids, which could lead to liver damage.

Preemie's intestines have slow motility and distend quickly, Sunshine says, because they have trouble absorbing many substances. The infant's intestinal lining can suddenly slough off for some unknown reason, leaving the bowel open to invasion by the baby's own bacteria. Milk provides a good growth medium for the bacteria; the bowel stops functioning and the baby's life is in danger.

Only with time does the proper panoply of intestinal enzymes develop, he says. Sunshine discovered one such enzyme lack that leads to dangerously high levels of ammonia in the preemie's blood.

Another problem facing premature infants is jaundice, which if it becomes severe enough will leave the jaundiced infant severely brain damaged. The yellowed skin of the infant is mirroring the buildup throughout the body of a bile pigment called bilirubin.

Preemies, infants of diabetic mothers and those with certain anemias most often require treatment for their jaundice.

-more-

4-4-4 Some jaundiced babies need exchange transfusions to remove the bilirubin. But most are just put under white lights, with little black patches protecting their eyes. It's been discovered that the blue portion of the rainbow that is light can best break down bilirubin.

Another problem premature babies often face is being born with a hole between the right and left sides of their hearts, which doesn't close as it should. This hole, a shunt used to bypass the undeveloped and non-functioning lungs (in the uterus, oxygen comes from the placenta, not from the lungs), is present in all babies, and closes shortly after birth in normal-term babies.

When it doesn't close, the baby may become blue because no blood is going through his underdeveloped lungs, which are putting up resistence to blood flow. When the lungs improve, then all the blood may flood into them, and congestive heart failure results.

If the doctors can't close the hole with drugs, then these tiny, bread-loaf size babies must have heart surgery.

The problems with barely-breathing lungs and poorly-pumping hearts lead to another major problem: bleeding in the brain.

"Somewhere between 40 and 50 per cent of babies born less than 34 weeks of gestation have intracranial hemorrhage of one degree or another," says Stevenson. "We really don't know what causes it."

The bleeds can range in severity from a localized, tiny bleed into the fluid-filled ventricles of the brain to a more massive bleed that seeps from the ventricles to the brain matter itself and may cause permanent damage.

"Over the last five to ten years, we've developed the technology to see how often it is happening," Stevenson says. "The encouraging thing we've found is that a number of babies who have had intracranial hemorrhages seem perfectly normal during the examination, and are probably going to be normal."

Drs. Barry R. Tharp, associate professor of neurology, and Thomas P. Clancy, clinical associate professor, have been using ultrasound and CAT scanners to determine which babies have intracranial bleeds. They have also been mapping the brain wave or EEG patterns of the preemies, and correlating this with the brain's maturation.

Another problem in the long list facing a preemie is poor regulation of the body temperature, resulting from an undeveloped nervous system, little fat and thus little insulation and fuel, and a poor response to cold stress, says Dr. Ariagno.

A small baby has a greater chance of survival if he is able to maintain a certain temperature, because his oxygen needs are lowest at that temperature, and his ill-equipped lungs aren't taxed. So, a preemie's first home is either in an incubator or under a radiant warmer, bathed in warming lights.

Finally, there is the ever-present danger of infection in the small, weak baby who is ill equipped to fight it. And all the tubes going into a premature baby to bring him food or medicine or to hunt for things that may be going wrong increase the probability that he will contract a bacterial or viral infection.

But in spite of the plethora of problems, babies like Jason are making it, and his orange bugs and green turtles may not have to go unnoticed for long.

"There is immense potential to develop outside of the uterus—in spite of some life-threatening stresses," says Dr. Ariagno. "Surprisingly enough, there are even some advantages. For instance, if the lungs of the infant are damaged, they have the capacity to recover to a great extent. They not only get bigger, they still can develop more."

What can be done with the new technology is dazzling, but not without problems. Doctors intervening to solve one problem can cause others unintentionally, and so must be ever-vigilant that while they're giving a helping hand to one system, they're not retarding the development or harming another.

But steadily, they're learning about these very young babies and their special problems.

"Our reseach is designed to put us out of business," says Stevenson.

Down the row from Jason is another baby who is going to go home very soon. She was born six months ago weighing a tad over two pounds. She smiles; she's a survivor. The odds are with Jason, too.

-more-

Challenges Facing Families of Premature Infants

Kristen and Karen Regelein, who are identical twins, will be three this June.

They kiss, and hold hands, and occasionally thwack each other, just like other little three-year old girls. But they're special.

Kristen and Karen were born three months early.

"When they were born, they weighed 2 lbs., 4 oz., but within a few hours, they had dropped down to a pound and a half," says their mother, Mrs. Marsha Regelein.

"Kristen was given a 50-50 chance at birth. Karen had such severe lung problems they told us she would not make it through the night. But she did.

"Then we just did it day by day. They told us so many times that she may die, I couldn't count them for you. We went up there a lot of times to say goodbye to her, but she was just too tough."

Marsha Regelein and her husband, James, are tough, too. Well-informed and articulate, she talks of the trying last three years with surprising calm.

"Kristen had bouts with apnea (intermittent cessation of breathing), and almost died a couple of times. And she was the healthier one; she came home after three and a half months, weighing less than five pounds.

"Karen stayed in the hospital six and a half months. She had much more severe lung disease, so when she did come home, she still required oxygen. There were all kinds of equipment and apparatus. We had to go down her nose and mouth with a suction machine to pull the mucus out about 20 times a day.

"Round-the-clock nursing was required the first year. The second year, we cut it down to two shifts a day; just last month we sent our last nurse away. We have not had our house to ourselves that entire time.

Caring for their little girls, the Regeleins have grown closer to each other, but that doesn't happen to all families. Often the strains put on a family by the financial burdens and the emotional drain of being at death's door repeatedly can destroy it.

"We have to deal with many complicated family problems," says Dr. David Stevenson, associate director of Stanford's neonatal intensive care unit.

The unit has its own full-time social workers, Charlene Canger and Jeannie Kelly.

The Regeleins', in the midst of their own struggle, have taken the time to counsel other families of premature, sick babies born at Stanford.

"Most families don't do very well. I don't blame them," says Mrs. Regelein. "It's an absolutely overwhelming thing to have even one baby, much less two, that you're told may not live."

Even the Regeleins, who repeatedly say how thankful they are, are not planning to have anymore children. Kristen and Karen are their first.

6-6-6

"We hadn't planned on having lots of children, but if we had, we probably would have changed our minds," says Mrs. Regelein. "They couldn't really guarantee me that these things wouldn't happen again, and I wouldn't put me, much less any baby, through that kind of trauma again.

"Kristen and Karen came out really well. They are fairly healthy, they're bright and personable. We are very lucky. I wouldn't want to press our luck."

If the toll on the families is too readily apparent, no one knows yet all the psychological effect on the fetus growing in a world of non-stop light and noise instead of in his mother's womb.

Also, the all-important parent-infant bond does not get a chance to form normally.

"We encourage parents to come into the nursery as soon as they can, and as often as they want," says Stevenson. "We try to foster the development of an intimate relationship between the parents and the baby."

But the sight of sick, fragile babies that at any time may die proves to be too much for some parents, who were expecting the nice, healthy Pampers baby.

If the baby does make it, there is still the grating worry of whether he'll have any handicaps.

"We just found out that Kristen has a fairly severe hearing loss that we had not known about." says Mrs. Regelein. "That would be devastating to another family, and for us, it's not pleasant. But in the list of all the things, we could have come out with, it's minor. She's bright, she's well and very sturdy.

"Karen, as sick as she was, has no retinal damage, no brain damage, no motor skill damage. Her lungs are in superb condition compared with even a year ago.

"For the first time since they've been born, I feel we know all the things that is wrong with them. We know all the things we have to do to fix it.

"Some of it is not real good news, but there are not a lot of question marks left anymore. And that's a real good feeling.

"There aren't many data to show you about what is going to happen to your baby. There aren't many people you can talk with because there are not that many people walking around with babies like ours."

"There is no question about it," says Dr. Stevenson. "We need to think of all these problems arising in newborn intensive care from an interdisciplinary point of view. Not only doctors, but clergyman, psychologists, even anthropologists are needed to help young families confronted with economic and psychological problems."

Mrs. Regelein says the girls helped her to be strong.

"I saw them doing better, because we were being strong. They really are a reflecion of your strength."

STANFORD—

The second combined heart-lung operation at Stanford University Medical Center was performed on a 30-year-old Binghampton, N.Y., man on May 1.

Charles Walker, who was born with a congenital heart defect and whose lungs had become damaged because of his poorly-pumping heart, had become seriously ill more than two and a half years ago. A team of four surgeons, led by Dr. Bruce A. Reitz and Dr. Norman E. Shumway, completed the four and a half-hour operation at 6 a.m.

Walker is now in the Hospital's intensive care unit in critical but stable condition. He will remain on a respirator for 24 to 48 hours before the attempt is made to let his new lungs begin breathing for him.

His new heart and lungs came from an anonymous donor.

"So far, we are satisfied that strategies developed with animals in our laboratory have proven successful in patients," said Dr. Reitz.

But, he cautioned, it is too early to judge the overall success of heart-lung transplants until more operations are done.

Walker has been waiting for a donor since April 3. He and his mother, Mrs. June Spangenberg, have been living in the Stanford area while waiting for the donor.

Mr. Walker is the middle son of five. He grew up in Newark Valley, New York, and now lives in Binghampton with his dog, Teddy.

Mrs. Mary D. Gohlke, of Mesa, Arizona, who received a heart-lung transplant on March 9, is in satisfactory condition 54 days after her operation. She is still in the intensive care unit, and slowly regaining her strength and stamina. She is on a physical therapy regimen.

This is only the fifth heart-lung transplant ever performed in the world. The other three were done between 1968 and 1971, but because of complications, none of the recipients lived longer than 23 days.

The 1972 discovery of the drug cyclosporin A has set the stage for the most recent attempts to replace at the same time both heart and lungs. Cyclosporin A circumvents two previously formidable obstacles in heart-lung transplants: the slow and imperfect healing of the windpipe and life-threatening infections.

STANFORD—

Medical students at Stanford University will join their colleagues nationwide in a National Day of Concern for Health on Friday May 8, 1981, declared by the board of trustees of the American Medical Student Association (AMSA).

The day is intended as a constructive protest to the Reagan Administration's proposed budget cuts in health related programs, according to Arturo Molina, president of the Stanford Medical Student Association.

Stanford medical students will assemble in the courtyard of the Medical School at noon and will then march across campus to White Plaza, culminating with a rally in front of the Old Union until 1 p.m..

Rally speakers will include Dr. John Steward, associate dean for Medical School student affairs; Count Gibson, professor and chairman of the Department of Family, Community and Preventive Medicine; Andre Burnett, guest professor at Stanford and expert on issues of minority higher education; and Silvia Corral, senior medical student.

Across the country, students will acknowledge the Day of Concern in many different ways, Molina says. In Washington, D.C., medical students have planned a march and rally, and seminars will be held at Yale, he notes.

Stanford medical students have also organized a postcard-writing campaign to key legislators. Information and postcards will be available at the rally, Molina says. The medical students hope to attract students, staff and faculty from around the campus to the march and rally, and they are seeking active participation of several other campus groups including the Stanford Premedical Society and the Stanford Progressive Alliance.

The Reagan Administration's proposed cuts "will affect mostly those citizens living at or below poverty levels," contends Molina. "Such actions will further diminish the already impoverished status of many underserved populations in this country," he adds.

According to the AMSA, three areas of potential budget cuts cause greatest concern:

-more-

- reductions in direct service programs,
- consolidation of current programs into block grants to individual states,
- elimination of reasonable loan programs to health professions students.

An AMSA statement asserts that a 25 percent reduction has been proposed in approximately 40 health and social service programs including community health centers, maternal and child health programs and migrant programs. Also on the list of proposed cuts, according to the AMSA, is Medicaid funding, by means of an interim cap on federal participation. The proposed cuts in 1981, they say, will amount to $353 million and in 1982 to $1.2 billion.

Related to health care funding reductions are massive cuts anticipated in environmental protection, occupational safety and health, family planning and mental health, and food stamps, the AMSA statement adds.

Health student loan programs are slated for drastic cuts, with a ceiling to be placed on the number of federally employed National Health Service Corps physicians.

"The elimination of reasonable loan programs to health professions students is likely to enhance the entrance barriers for low and middle income students as well as racial and ethnic minority students," the AMSA says. "This will ensure that in the long run, fewer communities will be provided health care practitioners and facilities through the NHSC," the AMSA statement continues.

"The proposed consolidation of current categorical programs into block grants to individual states will shift the responsibility for administration and provision of services from the federal to state governments, a change which many states are neither prepared nor committed to implement," the AMSA explains.

The National Day of Concern is endorsed by several other national medical student organizations, including La Raza Medical Student Association and the National Medical Student Association.

Further information can be obtained from students involved in planning Stanford's Day of Concern, including Arturo Molina, Pamela Steele, Silvia Corral and Michael Gurule. They can be reached at the Medical School's office of student affairs at 497-6951.

Editors Note: Mrs. Gohlke and her family have requested that neither pictures be taken nor interviews be given at this time. Condition reports will be provided by the News Bureau as requested. If the Gohlke family should change its mind, we will inform you.

STANFORD—

Mrs. Mary D. Gohlke, the 45-year-old Mesa, Arizona, woman who received a heart-lung transplant at Stanford University Hospital on March 9, was transferred from the hospital's intensive care unit to a general ward this afternoon (Wednesday, May 6). She remains in satisfactory condition.

Dr. Bruce A. Reitz, the cardiovascular surgeon who is in charge of the heart-lung transplant program, says that, although it is impossible to predict exactly, Mrs. Gohlke may be released from the hospital in three weeks.

Mrs. Gohlke, advertising director of the *Mesa (Arizona) Tribune,* received the first heart-lung transplant in humans in almost ten years, and the fourth one ever done in the world. She has survived longer after the operation than any of the other recipients, the longest of whom survived 23 days.

On May 1, a 30-year-old Binghamton, N.Y., man became the second person to receive a heart-lung transplant at Stanford. Charles Walker, who was born with a heart defect, is still in critical condition, but his recovery has been smooth so far.

Mrs. Gohlke, who had pulmonary hypertension, has spent the 59 days since her operation in the intensive care unit slowly regaining her strength and stamina.

Ten days after the surgery, she was beset by a mild rejection of the new heart and lungs, but that was completely controlled within a week, and her recovery has been steady, although slow, since.

The 1972 discovery of the drug cyclosporin A has set the stage for the most recent attempts to replace at the same time both heart and lungs. Cyclosporin A reduces the possibilty of two previously formidable problems in heart-lung transplants: the slow and imperfect healing of the windpipe and life-threatening infections.

Mrs. Gohlke's operation was the culmination of more than two years of experimental work in primates, conducted by Reitz and his associates in the Stanford cardiovascular laboratory.

The operation is still an experimental one, and only time and experience will tell whether it will be possible to do it routinely. The Stanford team may do three to four of these operations a year, Reitz estimates.

STANFORD—

Stanford police have completed an investigation into the citizens arrest and alleged injury of a psychiatric outpatient by security personnel at Stanford University Medical Center, a spokesman announced Tuesday.

Stanford Police Chief Marvin Herrington said he has turned over investigative material to the Santa Clara County District Attorney's Office.

The action stems from an April 27 incident in which the patient struggled with Medical Center security personnel.

The 32-year-old Palo Alto man was treated and released from the Stanford University Hospital emergency room suffering from a broken or dislocated finger, three broken teeth and bruises around the eye.

The patient was issued a citation by university police officers for investigation of fighting in a public place and assault and battery.

Herrington said he was informed by the District Attorney's office that all allegations against the patient were dropped.

"We were asked to conduct a followup investigation by the District Attorney to determine whether charges should be brought on either side. We conducted the investigation and turned over all the materials," Herrington said.

The chief said he offered no opinion on whether further action should be pursued.

Stanford University Police serve as Santa Clara County Sheriff's Deputies and have no administrative connection to the hospital security force.

Richard Pettingill, assistant administrator, said the hospital was conducting its own internal investigation into the incident.

Herrington said a receptionist in the Department of Psychiatry Outpatient Clinic called Medical Center security officers after a patient, who had just completed a visit with his doctor, demanded loudly to return to the inner office.

Three security officers arrived and they were later joined by a supervisor who asked the man to leave.

The patient conceded he struck the security man, whom he said had kicked a backpack he had brought to the office, Herrington said. The security man said he had picked up the patient's backpack to help him leave the office.

According to statements, the patient and security man, who was not injured, exchanged further blows.

STANFORD—

On the surface, the picture looks bright for women entering medicine. The number of women physicians in the U.S. has risen steadily in the past decade, and 25 percent of today's beginning medical students are women.

But, upon closer scrutiny of the facts, one discovers different trends. In a recent interview, Laura Esserman, a third-year medical student at Stanford, and Dr. Joan Kendig, Associate Professor of Biology in Anesthesia, discussed special problems they see for women in medicine.

Presently, said Esserman, less than 10 percent of American medical school faculty at all ranks are women (lower than the percentage for 1965-66). There is not one full dean who's a woman in any medical school in the country.

At Stanford Medical School, the number of women faculty members has in fact remained at approximately 10 percent since 1971. And of these, most are assistant or associate professors. "This past year, *no* women faculty at the School were promoted."

As Esserman sees it, part of the problem lies in the fact that women, traditionally, have not opted for careers in academic medicine, as physician researchers; rather, they have chosen private practice—for reasons not altogether apparent.

"We feel," she said, "that perhaps the existing structure has made it difficult or impossible for many women to choose academia."

Kendig explained that most women are about 30 years old when they complete their residencies. This is also the time they may want to start families, and that's where complications set in.

It is critical *not* to take time off if one wants to pursue an academic career. Explained Esserman, "Once you've gotten out of the mainstream it's very difficult to work your way back into the tenure track." So for many women, it comes down to choosing between family and work.

"I don't think very many men would accept a career on such an either-or basis," commented Kendig.

Another obstacle to academia women have faced, said Kendig, is that less often than men are they encouraged to think seriously about paths for career advancement. "The important question is, what do they have to do now so that they have the option of moving into job "X" five years down the line, and conversely, what's going to shut them out from that option?"

Students should consider all the specifics, said Kendig, and make sure they have clear, convincing documentation in their dossiers. "If you look around at many women, they have just sort of fallen into their careers."

One reason for this, suggested Esserman, is that women have not had the advantage of being part of the "old boy network" so common to professional circles of men.

"I think what you plan to do in your career is often based on a role model." And except for the basic sciences, she said, almost all clinical medicine is taught by male faculty. "So, maybe subconsciously, you don't really think that's an option open to you."

Therefore, said Kendig, it's important to watch how the University is doing, "not only in getting women into beginning ranks, but in promoting them in comparison with men.

"One problem, of course, is that we're getting women in just when opportunities for everyone are being very tightly restricted. It's a tough time."

And many appointments, said Esserman, are very political decisions. "A lot depends on whom you know." Often, women doctors simply don't have the luxury of extra time to stay and talk with colleagues at the end of the day. They have to go home to their families.

-more-

Said Kendig, "If you're asked by a search committee to come up with a name for chairman of the department, you think of good old Joe Blow, who's been around, who's here all the time, and quite obviously a big part of his department. You don't think of Jane Smith, who vanishes at the end of the day and whom you only see professionally."

The few women physicians who do enter academia, said Kendig, are often so swamped with committee duties that they have little time to spend with individual students. "We get asked to serve on every committee, many times because we're women."

And this becomes a dilemma. "We're torn," said Kendig. "Many of these committees are very important, and one really feels a duty to serve.

"On the other hand, women and also minority faculty at this university may impede their own careers by being too generous. Because committee time is not rewarded the way research output is, and there are only so many hours in a day."

It was the glaring paucity of female role models on the Stanford medical faculty which prompted Esserman and another medical student, Barbara Paul, to organize a recent conference for women, entitled, "Designing your Medical Career."

The program was sponsored by the Katharine McCormick Society, an organization of Stanford women faculty and medical students, as well as the American Medical Women's Association and the American Medical Association. It provided an opportunity for women in medicine to think about and discuss their career plans.

Later, reflecting on the all-day program, Esserman commented, "The conference wasn't on how to make it in a man's world, it was how to make it as a woman, in a predominantly male organization."

One proposal for change, she said, is in the area of work options. If women—and men—had more flexibility in arranging their schedules, happier and more effective professionalism could result.

Job sharing and shared residencies are two ways to go, said Esserman, for women who want to keep abreast of their fields while raising families. Most successful residency-sharing programs, she explained, work on a rotating basis, with the two physicians alternating one month or two, on and off the job. Job sharing requires either both partners on duty at the same time, or working alternate days. And of course, said Esserman, for such arrangements to succeed, the two partners must be compatible.

Job sharing may benefit the institution too, said Esserman. "If one person is out sick the other can cover. And usually, both end up putting in more than their official half-time." Besides, she added, if physicians are not encouraged to consider raising a child important, or are not given the opportunity to try it, that is counterproductive to the medical field.

But work options, stressed Esserman, are not just for raising families. A shared residency, she said, seems a natural for anyone deeply involved in research. "Otherwise, unless you take time off during your residency, you're essentially quitting in your research area."

Agreed Kendig, "This is something that all physicians aiming for an academic career face, just how to fit their research time in with their clinical training time. It's a very difficult tightrope act."

Presently, she noted, several women in Pediatrics share residencies. And two physician specialists share one full-time position in the Pediatrics Ambulatory Care Center. In the Department of Psychiatry, both men and women have in the past taken extended residencies in order to have time for other activities.

Commented a sharing resident in Pediatrics, "One disadvantage I've found is that you can feel a bit rusty after being away a couple of months, and there's a certain anxiety associated with re-acclimating. But overall, it's working out well. It's really what you make out of it."

Many obstacles to job advancement, believe Esserman, are related to the frequent misconception that anyone involved in job sharing is only half committed. "Changing this attitude, I think, is just a matter of getting more good people to do it, and also a matter of time."

Dr. Lawrence G. Crowley, Vice President for Medical Affairs and Acting Dean of the Medical School, was the only male panelist at the conference. "He was extremely supportive," said Esserman.

-more-

Addressing certain administrative problems he sees with shared residencies and job sharing, Crowley nonetheless said he'd be more than happy to look at proposals, and possibly to establish more secure work option programs.

He spoke, however, of natural resistance from members of the establishment, the perceptions of reverse discrimination when most sharers are women, and the difficulties in procuring funds from granting agencies.

"In general," he said, "Stanford is committed to seek new knowledge and experiment with change. Creativity is welcome. Restraint is pragmatic."

Certain departments, he said, would not lend themselves readily to shared residencies. And it's difficult to make an effective evaluation when comparing a part-timer with others who move at a faster pace.

Crowley pointed out that an academic career in medicine entails both teaching and research. And while it may be relatively easy to share a teaching load, conducting research on such a basis—without duplication of effort—is trickier. (Many participants at the conference, however, felt that research is ideally suited for a collaborative effort by two people in a job sharing position.) A long-term trade-off for the individual, of course, is decreased income.

Crowley did, though, have several suggestions of ways to work towards the kinds of change discussed at the conference. He recommended the development of small, well-planned pilot projects with built-in criteria and methods for evaluation. Special term support, he said, should be sought for such projects. Concerning problems of delayed tenure for job sharers, he said, the entire tenure system as it stands is currently under review.

Meanwhile, said Esserman, the past shows us that the growing number of female medical students should not be interpreted as promise of greater prominence among women faculty members in the next decade or two.

Women began to enter the field of medicine in numbers, she said, in the late 19th and early 20th centuries. In the beginning, it seems, there was quite a bit of solidarity among them. "But later generations began to worry more about individual professional identity, and many group goals were no longer shared. Women neglected to preserve themselves as part of the medical establishment."

And now, said Esserman, "No one will roll the stones out of our way." Young women, she pointed out, must know how the medical power structure works in order to get a hand in it.

Both Kendig and Esserman stressed the importance of child care and other household support as prerequisites for women's advancement in medicine. Said Esserman, "We must not be afraid to hire people to do the things we don't have time for."

On-site day-care, said both women, would be a very worthwhile project. "But," recalled Kendig, "we tried a number of years ago to get a child care center started here, and got absolutely nowhere."

In fact, a task force was recently formed at the Medical Center to consider the feasibility of various child care services as part of a long-range human resources plan. However, because of tight budgetary conditions, the task force is presently concentrating its efforts on evaluating other methods of assisting employees with child care, such as providing information on existing facilities. According to Carol Ann Bergman of Personnel, the committee will continue to evaluate on-site feasibility for the future.

Kendig has suggested to Crowley and the Office of Student Affairs that the conference on women in medicine ought to be made an institutional responsibility in the future. "Our students obviously need it. We had a fantastic turnout and a very enthusiastic response."

Based on the success of the conference, Esserman concluded that counseling and forums for discussion are very important for both men and women in medical school.

"I don't think people really sit down much to discuss what's stressful. If they did, they'd feel much freer and make more effective physicians." In fact, she noted, women actually tend to have the edge over men in discussing the daily anxieties they face. "So this could be the beginning of something really important for us all."

STANFORD UNIVERSITY MEDICAL CENTER
News Bureau Stanford, California 94305

STANFORD—

Like a scene from years past on the Stanford University campus, about 200 medical students and a sprinkling of faculty members held a noon march and rally at White Plaza on Friday, May 8, in protest of the Reagan Administration's budget cuts in health related programs.

Carrying signs that read "we need M.D.'s, not M.X.'s," and "a healthy economy needs a healthy society," the marchers drew many stares and occasional applause as they traversed the campus enthusiastically chanting "health care is a right; no more budget cuts."

The rally was one of many sanctioned at medical schools nationwide by the American Medical Students Association (AMSA), according to Arturo Molina, president of the Stanford Medical Student Association and one of the organizers of the protest.

Major cuts in direct service health care programs and elimination of low-interest loan programs to health professions students were the focus of "The National Day of Concern," said Molina.

According to an AMSA statement, the administration will put a brake on Medicaid spending by means of an interim cap on federal participation, with cuts in 1981 equalling $353 million and in 1982, $1.2 billion.

Also, the AMSA says that reductions in health student loans, loan rates at only three percent above the Treasury rate, and a federal ceiling on the number of National Health Service Corps scholarships are likely to enhance entrance barriers to the health professions for low and middle income students and racial and ethnic minority students.

Through a statement read by Molina, Dr. Lawrence G. Crowley, the Medical School's vice-president for medical affairs, and Dr. John P. Steward, associate dean for students, said: "sudden and substantive cuts in federal support will unquestionably jeopardize programs that have demonstrated merit . . . of extreme importance is that we maintain access to the healing professions for individuals from disadvantaged backgrounds. Unfortunately, many of the proposed legislative changes could result in fewer physicians coming from disadvantaged backgrounds."

-more-

"A blitz has come over us in the past three or four months," said Dr. Count Gibson, professor and chairman of the Department of Family, Community and Preventive Medicine, addressing the crowd which swelled to about 300 as lunchtime browsers from the nearby Spring Faire paused to listen to the speeches and fill out protest postcards to mail to legislators.

"We have been caught off guard but we have to let our congressmen and state legislators know that these cuts will cause our neighborhood health centers to starve and close. Once they are closed, how will they re-open? We have to save these institutions in order to save lives."

The Administration plans to consolidate about 40 health and social service categorical grant programs (including migrant programs, community health centers, and maternal and child health programs) into block grants to the states with cuts for 1982 totalling 25 percent in current dollars, according to the AMSA.

"We must begin to write to our state legislators now," said Silvia Corral, a senior medical student who addressed the rally. "As medical students, we're not used to being active in politics. Some of my colleagues say that medicine shouldn't be political. But we have to protest now," she continued. "The Reagan Administration is hitting us like a fly ball."

"It's a time of crisis," said Andre Burnett, a guest professor at Stanford and an expert on issues of minority higher education. "When you can't be assured of health care tomorrow, when you can't be assured of educational opportunities tomorrow, it's a crisis."

Related to health care funding reductions are massive cuts anticipated in environmental protection, occupational safety and health, family planning and mental health, and food stamps, the AMSA adds.

All of the speakers exhorted march participants to write to their legislators, and many students were busily filling out postcards as the rally concluded.

"This is going on at medical schools across the country," commented Molina. "I think it's a very substantial turnout," he added. "It looks like about half the medical student body to me."

FOR IMMEDIATE RELEASE

STANFORD—

Jessica Raphael spends each Wednesday afternoon in the same pediatric ward where as a child she mounted a successful battle against scoliosis.

The Gunn High School senior may or may not be typical of the 55 junior volunteers at Stanford University Hospital, but Tuesday night (May 11) she was among five of the Candystripers honored for dedicated service.

Receiving scholarships for service in excess of 200 hours were, besides Raphael, Jamie Flaxman, Alice Mansell and Victoria Anderson of Castilleja School; and Susan Benham of Palo Alto High School. All of the winners are seniors.

Mansell accumulated the most hours—295—and has worked in both patient services and the emergency room.

Both Anderson and Raphael say they plan careers in nursing, and for the latter the choice isn't really a decision.

"I can't really see myself working any place else other than in a hospital," she explained.

While in sixth grade, Raphael completed the first of several hospitalizations for scoliosis, a lateral curvature of the spine.

"I had some really good experiences with the people here then, and I decided I wanted to come back here to work," she said.

"Some of the most rewarding times now are times spent with the kids who have the same thing I had. It kind of helps to talk with someone who has been through it," she adds.

Of course most of the children, aged six months to 18 have other diseases, and Raphael says she especially enjoys working with the youngsters who speak only Spanish."

"Many of these kids don't have anyone who can talk with them, so it's really great to see them smile and respond when they are able to be with someone who speaks their language."

Raphael studied Spanish in school and participated in a summer exchange program in Oaxaca, Mexico. And smiling she says that much of her Spanish practice these days result from conversations with her boyfriend, Javier Gil, and his Spanish-speaking family.

Colette Case, a recreation specialist in the pediatric ward, praises the work of Raphael and her colleagues.

"There just wouldn't be as much one-on-one contact with the patients without the volunteers," says Case.

Candystripers such as Raphael play games or talk with the patients.

Case says that often activities are selected to enhance whatever difficulties the patients might be having. For example, the volunteer might be encouraged to guide a child recovering from a stroke to try fingerpainting to help regain dexterity.

STANFORD—

"Cardiovascular Nursing in the 80's: New Frontiers" will be the topic of a national clinical nursing seminar, co-sponsored by Nursing'81 (a nursing journal published monthly) and Stanford University on September 9 and 10, 1981.

To be held in San Francisco at the Saint Francis Hotel, the seminar will focus on guiding the professional nurse from current principles related to care of cardiovascular patients to potentially advanced principles and skills of the future.

An optional third day, September 11 (limited to 200 participants from the first two days), will include a visit to Stanford University Hospital where workshop sessions will take place.

Topics to be covered at the seminar include: cardiac rehabilitation and patient education; cardiac surgery and transplantation: Where We've Been and Where We're Going; the child with heart disease; nursing management of the cardiac transplant recipient; and others.

Speakers will include Norman E. Shumway, M.D., Ph.D., professor and chairman of Stanford's Department of Cardiovascular Surgery; Jay Mason, M.D., assistant professor in the Division of Cardiology; and Linus Pauling, Ph.D., Nobel laureate from the Department of Chemistry.

Members of Stanford's Nursing staff participating on the faculty will be: Carol Ashton, Elaine Baylis, Janice Bridgham, Joan Caldwell, Paula Caltagerone, Marty Douglas, Kathleen Grady, Eleanore Hedenkamp, Joan Mersch, Joyce Miller, Mary Jo Schuermann-Oeder, Margaret Pfister, Julie A. Shinn, Katherine M. Vivenzo and Lois Welches.

Fees for those who register before July 1 are $150 for the two-day seminar, and $35 for the optional third day (to be filled on a first-come, first-served basis). Registration after July 1 will be subject to a 10 percent surcharge.

Fees include all materials distributed at workshop sessions, plus coffee and luncheons. The third-day fee includes motorbus roundtrip transportation between the Saint Francis Hotel and Stanford University, continental breakfast and luncheon.

All interested nurses can register by contacting Mr. John E. Kelly, Nursing'81, 132 Welsh Road, Horsham, PA 19044, (215) 657-4600.

STANFORD—

Dr. Dora Goldstein, professor of pharmacology at Stanford University Medical Center, has been awarded the second annual Award for Scientific Excellence by the Research Society on Alcoholism in recognition of a decade of "outstanding contributions" toward the understanding of the biology of alcohol tolerance and dependence.

She received a $1000 award and a plaque.

Dr. Goldstein, the immediate past president of the Society, has delved into those chronic components of alcoholism that are due to the drug itself, and not those owing to the psychological problems of the drinker.

She's explored the hand-in-glove relationship of alcohol dependence and tolerance, testing the premise that these are adaptive phenomena. Physical dependence and tolerance to the drug occur because the human or animal adapts to the alcohol's presence and functions fairly well in spite of its being there.

The body actually changes some of its inner workings to accommodate the alcohol and becomes tolerant of the drink. But while the body now can tolerate the alcohol, it also needs the drug around to provide the conditions in which it is geared to operate, Goldstein says. And therein lies the rub.

Dr. Goldstein, in order to get a handle on a syndrome with many components, developed a simple system to produce rapid alcohol dependence in mice.

Sorting out the many components of alcoholism in man is a next to impossible job, says Goldstein.

"Alcohol addiction in man develops over a period of years, and is often accompanied by malnutrition and disease," Goldstein says. "It is difficult to study alcohol dependence when other diseases are present."

So scientists look to animals for clues about the physical parts of alcoholism. Mice are choice research subjects because they become alcohol-dependent in just two to four days.

Dr. Goldstein figured out that mice could be kept in a drunken state if vapor of alcohol was wafted into their air-tight plastic cages. After a few days in such alcohol-laden air, the mice are made to go cold turkey and their withdrawal symptoms are closely measured and recorded.

-more-

2-2-2

Certain strains of mice develop convulsions when the alcohol disappears. (That only select strains convulse implies there is a genetic factor in alcohol dependence.)

Dr. Goldstein and her colleagues found that the intensity of these convulsions was related to the amount of alcohol the mice had had over time.

After Dr. Goldstein demonstrated that dependence on alcohol is, at least in part, physical, she turned her attention to the changes that occur in the cell membranes of alcoholic mice.

Alcohol, which is a small molecule, appears to work by slipping into cell membranes and altering how they operate, says Dr. Goldstein.

Working with her associate, Dr. Jane Chin, she discovered that alcohol at first makes cell membranes more fluid. But as the mice develop tolerance, their membranes are no longer readily deformed by alcohol. Instead, they stiffen up, and in alcohol's presence behave rather normally. The two researchers found this to be true in both brain and red blood cells.

Drs. Goldstein and Chin think that this imperturbability of the membranes may be due to the increased amounts of cholesterol that they have found in the alcohol-accustomed membranes. Working with artificial membranes in a test tube, they've discovered that the more cholesterol these membranes contain, the greater is their resistance to the membrane-moving effects of alcohol.

Dr. Goldstein is now investigating what happens to the cholesterol-cargoed, adapted membranes when the alcohol goes away. She is also exploring if the alcohol itself assists cholesterol's collecting in the cell membranes.

Dr. Goldstein's hope is that by better understanding the physical changes wrought by alcohol, one moves closer to minimizing the all-too-apparent damage done by the drug.

"Addiction is becoming a lot less mysterious than it used to be," says Goldstein. "Although we still don't understand the psychological components very well, we're getting to understand the biochemical and pharmacological components really nicely."

The Research Society on Alcoholism, a component group of the National Council on Alcoholism, has about 300 active members. Its aim is to increase support for alcohol reseach and to enhance communication among alcoholism researchers, says Goldstein.

STANFORD—

Charting blood flow in the heart and great vessels of the body and mapping the connections the visual system makes in the brain as it develops are among the research interests of the seven Stanford junior faculty members recently selected for biomedical research awards.

Diana Guthaner, M.D., of the division of diagnostic radiology; Lorin K. Johnson, Ph.D., of the department of pathology; Laurence J. Korn, Ph.D., of the department of genetics; Mervyn Maze, M.B., Ch.B., and Susan Rice, Ph.D., both of the department of anesthesia; Ron G. Rosenfeld, M.D., of the department of pediatrics; and Carla J. Shatz, Ph.D., of the department of neurobiology have received start-up money from a National Institutes of Health grant awarded to the School of Medicine.

Each year, funds are distributed to junior faculty members to assist them in establishing research programs. Dr. Eric Shooter, chairman of the department of neurobiology, is the head of the faculty committee that selects the recipients.

Dr. Guthaner wants to characterize the blood flow in the heart, the body's great vessels, and coronary artery bypass grafts using computed tomography, a CAT scanner. Her aim is to find out in a non-invasive way whether a person is developing problems that could lead to a heart attack.

Dr. Johnson is trying to better understand the relationship between atherosclerosis, or hardening of the arteries, and blood cells called platelets. He is culturing in the lab two types of blood vessel cells: the endothelial cells that line the arteries and the underlying smooth muscle cells. He is watching how the platelets affect the cell types, and if medication can effectively combat the proliferative effect platelets have on the smooth muscle cells.

Dr. Korn is exploring what regulates the expression of genes in higher animals during their development. He is using the South African clawed toad as a model, and is probing whether proteins or other factors determine whether or not, in the course of development from the egg to a toad, the ribosomal RNA is made.

How the hormone epinephrine, used, among other things, as a vasoconstrictor and heart stimulant, and the common anesthetic halothane act together to cause irregular beating of the heart is what Dr. Maze is trying to discover. Although either substance alone can cause irregular beating, or arrhythmias, together they can create a life- threatening situation.

Dr. Rice is investigating how a drug for tuberculosis speeds up the metabolism of a fluoride anesthetic. Too rapid breakdown of the anesthetic releases an excess of fluoride into the body, resulting in transient damage to the kidney.

Growth disorders in children is the primary concern of Dr. Rosenfeld. He grows cells from children with growth disorders in controlled conditions in the laboratory, and tests how hormones, such as somatomedin, affect them.

Dr. Shatz is mapping the connections the visual system in the cat makes as it develops. During the prenatal period, the visual systems of cats and humans make similar connections, and so she hopes to get clues about humans from studying cats.

STANFORD—

The time has come for biomedical researchers and government-granting agencies to realize that high-powered, high-cost instruments—increasingly key tools in the biomedical sciences—are most efficiently used through shared-facilities, says Oleg Jardetzky, director of the Stanford Magnetic Resonance Laboratory.

Jardetzky is the first president of the Association for Advanced Technology in Biomedical Research, a group composed of directors of public-supported laboratories that are national or regional centers for research. The group recently formed to promote the use of sophisticated technology in biological and medical research and in medical practice, and to get the message out that sharing means saving.

Dr. Carl Djerassi, Stanford professor of chemistry, and Dr. Edward H. Shortliffe, Stanford assistant professor of medicine are members of the Association's steering committee.

Jardetzky says that costs of technologies such as nuclear magnetic resonance, synchrotrons, million-volt electron microscopes, and computers programmed for graphics or artificial intelligence, run in the six figures. They're just too expensive to be given to the individual investigator; the answer lies in regional or national facilities, he says.

"Biomedical researchers must start sharing these costly resources, as the physicists and earth scientists have done for a long time," he says.

The quality, quantity and development of scientific instruments available for research in the United States have been declining during the last decade. The drop can be pinned on inflation and the shrinking research dollar, coupled with a doubling in replacement costs of equipment, which is increasingly more powerful and sophisticated and, thus, in greater demand, he says.

Super high-technology in biomedical reseach has come into its own during the past decade, providing ways to tackle problems previously unanswerable.

"Scientists in their own labs armed with test tubes and centrifuges are obviously making tremendously valuable contributions," Jardetzky says. "Yet, there are aspects of biomedicine that we'll never understand without high technology. For instance, we'll never know how molecules function until we know how they move, and for that we need a synchrotron, or nuclear magnetic or electron spin resonance."

-more-

Although there are some shared facilities around, they are still relatively few, he says. Approximately 60 such facilities will be members of the new Association, says Jardetzky.

Those existing are the work of the 20-year-old Biotechnology Resources Program of the Division of Research Resources of the National Institutes of Health (NIH) and of the instrumentation program at the National Science Foundation.

The NIH program has been at a constant level of funding since 1967, says Jardetzky, which translates to a considerable cut in funding given that the inflation in instrument costs often exceeded 100 percent during this period. And recently, Congress proposed cutting its funds much more severely than most other NIH programs, he says.

"The program all along has been on a back burner," says Jardetzky. "Some facilities are now being phased out altogether. The government must become aware that certain types of work will not be done unless there is a sharing by individual investigators."

The shared facilities that do exist are scattered over the nation, but Stanford with its five has by far the most. The largest number found at any other university is two.

Stanford's national facilities are: the Stanford Magnetic Resonance Laboratory (SMRL), headed by Jardetzky; Stanford University Medical Experimental Computer for Artificial Intelligence in Medicine (SUMEX-AIM), headed by Drs. Edward Feigenbaum and Shortliffe; Stanford Synchrotron Research Laboratory (SSRL), headed by Dr. Arthur I. Bienenstock; the Mass Spectroscopy Laboratory, headed by Dr. Carl Djerassi, and the Stanford Electronics Laboratory (SEL), headed by Dr. James D. Meindl.

STANFORD—

Lane librarian Claire Still, the resident expert on the history of medicine, retired this month after almost twelve years at the Lane Medical Library. But you could scarely wink before she was exploring another page of history—a train trek across Canada.

Ms. Still, a small, slim woman, whose twinkling blue eyes behind her brown-framed glasses grow big when she talks of the trip, is a self-taught history of medicine buff.

She learned all she could at every chance she could, says Peter Stangl, the director of Lane, and her retirement is a great loss to the library. None of the other librarians has the specialized knowledge that Ms. Still has.

She says her interest in the history of medicine developed naturally. Before enrolling in Library School at the University of California, Berkeley, in 1969, she had been a medical social worker for 25 years, and among other things worked with the American Red Cross during World War II and travelled to various parts of the country during the polio epidemic of the '50's. She also has two brothers who are physicians.

Last September, after years of handling most of Lane's original cataloging of rare books and reference questions about history, she officially became the history librarian of Lane.

During this past academic year, she has undertaken several ambitious projects. Lane has some 6500 rare books, some dating to the early 15th century, according to Still. She has developed a computer listing of the subjects and chronology of Lane's pre-1850 books.

She also has organized and cataloged three major collections of papers: that of Dr. Russel Lee, the founder of the Palo Alto Clinic, Dr. Ray Lyman Wilbur, who was dean of the School of Medicine from 1913 to 1916 and became Stanford's third president in 1916, and Dr. William S. Hunter, a longtime physician at Kaiser.

In addition, she has helped Dr. Alan Koslow, a resident in surgery, catalog and photograph the considerable collection of medical instruments that Lane has acquired over the years.

-more-

A particular interest of hers has been in the history of Bay Area women physicians. In 1976 she wrote an article for the Stanford M.D. on Alice Higgins, the first women graduate of the Medical College at the Pacific, predecessor of Cooper Medical College and of the Stanford University School of Medicine.

Last year she aided those editing *Victorian Women,* which was published by Stanford University Press.

Ms. Still's fascination with history does not stop at medical history. She is also a member of the Stanford Historical Society and historical societies of Menlo Park and Palo Alto. Her special interest is the oral histories of long-time area residents.

Ms. Still has also been active in the Association of American University Women, the Medical Library Association and the Northern California Medical Library Group.

She grew up and went to college in Lincoln, Nebraska. After receiving her bachelors degree from the University of Nebraska in Lincoln, she earned a masters in social work from Catholic University in Washington, D.C.

She has worked as a medical social worker at, among other places, Walter Reed and Georgetown University hospitals in Washington, D.C. and at Stanford University Hospital. She was also the social service director of a rehabilitation center in Omaha for over six years.

Since her switch into library science, she has worked at Lane.

When not travelling or chronicling the past, Ms. Still likes to play bridge and do needlepoint.

After her seven-week trip across Canada, Ms. Still plans to return to her Menlo Park home, and to keep on learning all she can about medical history, and other kinds too, for that matter.

STANFORD—

Dr. Keith Taylor, professor of medicine at Stanford Medical School, on July 1 will become Director General of Great Britain's Health Education Council, a semi-autonomous organization that advises the British government on priorities and programs in mass health education.

Taylor will take a leave of absence from Stanford at the end of the academic year in order to fill his new position.

A gastroenterologist and nutrition expert who holds the George Deforest Barnett Professorship in medicine at Stanford, Taylor will succeed Alastair Mackie in the post. The appointment was made by the Secretary of State for Health and Social Services of the British government.

The Council, with a yearly budget of five million pounds, carries out national, local and regional public information campaigns "to educate people to look after their own health," Taylor explains.

Much of the Council's information is conveyed directly through the mass media outlets of television, radio, newspapers, and magazines, explains Taylor. But schools, the National Health Service network and other organizations also cooperate in promoting health education information and materials, he says.

"One of my major efforts will be in the medical schools, to boost the health education training of doctors," notes Taylor, who will be the first medical professor to hold the Director General post since the 32-member Council was formed in 1968.

Specific areas he expects the Council to emphasize include smoking, alcohol consumption, and exercise. Target population groups are especially the very young (preschool and school children) and the late middle-aged (those around 60 years of age), particularly in the lower of the five social classes recognized in England, Taylor says.

In a sense, says Taylor, Britons have less incentive than Americans to stay healthy, since necessary health care services are guaranteed at no direct cost.

And since health services in Britain are uniformly provided to people of all ages and all social classes through the National Health Service, improving Britain's national health is largely a matter of better health education along with an increased appreciation of preventive measures that may forestall disease, Taylor believes.

-more-

Health maintenance organizations, or HMO's, (subscription health care groups that have been growing in the U.S.) have not realized their potential in this area, he claims.

By lowering subscription rates for members who participate in health education programs, HMO's have an opportunity to offer persuasive financial rewards, not available in the British system, to promote better health habits.

Taylor, 56, was born in London and received his general and medical education at Oxford University. He has been on the Stanford faculty for the past 18 years and was chief of the medical service at the Palo Alto Veterans Admininstration Medical Center from 1968 to 1978.

Taylor has been a strong advocate of increased research in human nutrition throughout his career, and he maintains that nutrition research is one of the most neglected areas of modern science. Promotion of adequate nutritional standards, in the home as well as in institutions such as schools, is another area he expects the Council to focus on.

Taylor held a Guggenheim Fellowship in 1971 and traveled extensively in Australia, Southeast Asia and Europe, studying systems of medical education and programs in human nutrition. Among his published works are papers on the absorption and transport of vitamin B12, and the immunological aspects of imflammatory diseases of the gastrointestinal tract. He is a member of numerous professional societies in the United States and in Britain. He is also a fellow of the Royal College of Physicians.

Of his new position, he says "it represents part of my interest that I have not had a chance to apply in a practical way."

STANFORD—

Some mammalian tumor cells are able to manipulate their immediate environment in such a way as to prevent the body from fighting off the tumor by immunological methods, according to a report in the May 22 issue of *Science* magazine by researchers at Stanford University, Brown University and the Beth Israel Hospital, Harvard University.

The key to this successfully evasive maneuver of tumor cells lies in their secretion of a membrane substance that promotes coagulation, or blood clotting, in the immediate vicinity of the tumor cell. This "mini blood clot" affords the tumor a dense, protective shield from the immune system's armory of disease-fighting proteins, the antibodies.

Dr. Steven Quay, the Stanford member of the research team that made this discovery, says these recent findings could provide an avenue for cancer therapy.

Quay says that for some time it's been appreciated that although people produce antibodies to growing tumors within them, the antibodies seem ineffective and unable to destroy the tumor cells. But researchers have not known why the normally powerful immune system has been stymied by tumor cells.

Only last year, two of Quay's colleagues from Beth Israel Hospital (Drs. Harold and Ann Dvorak), along with other researchers at Harvard, showed that tumor cells are able to change the environment right around them, the "microenvironment," in a way that incapacitates the immune system. They made the key observation that a barrier surrounds the tumor, forming what they called a "cocoon," isolating the tumor from the rest of the body. The barrier consists of fibrin, the primary material of which blood clots are made.

Quay and his colleagues now have shown that a substance found in the surface membrane of the tumor cell speeds the formation of these mini-blood clots and that this substance is biochemically different from the usual components of blood that activate and speed the clotting system (called procoagulants).

At least this is true in the two guinea pig tumor cell lines and the one human tumor cell line the researchers have so far investigated. Quay's partners in the research included the Dvoraks, and Drs. N. Orenstein, P. Hahn and A. Bitzer from Harvard, along with Dr. A. Carvalho from Brown University.

-more-

2-2-2

The researchers think this new information opens up several novel possibilities for therapeutic tacks to combat cancer. Administration of a general anticoagulant drug would be dangerous, Quay points out, because in order to have a dose high enough to prevent clot formation in the region of the tumor, the patient would run the risk of hemorrhage throughout the body.

But an alluring possibility involves finding a way to manipulate the tumor's coagulation system to prevent the microclots from forming, he suggests. This would have the effect of enhancing the patient's immunity because the natural anti-tumor antibodies circulating in the patient's blood could then get at the tumor cells.

The tumor-specific procoagulation factors that Quay and his colleagues have discovered are not yet completely characterized. "Anything that increases the rate of coagulation is called a procoagulant factor," he observes. "Until we know more about it, we can't call it anything else," he says. But it's most likely one of two types of compounds. "We know it comes from the plasma membrane, which is made of proteins and lipids," he says.

A possible therapeutic strategy would be to inactivate the procoagulant substance, says Quay, by a neat double-cross using the immune system. Once the procoagulant substance is purified, it can serve as a mold for designing an antibody to bind it specifically. The specificity of the antibody would prevent it from binding the blood's usual clot-promoting substances and interfering with the normal coagulation process, while permitting it to incapacitate the tumor-produced clotting substance.

The localized clot-promoting ability that Quay and his colleagues have observed is not unique to cells from solid tumor masses, he adds. Preliminary results from new experiments indicate that cancer cells from patients with leukemia also have procoagulant activity. It could be a universal phenomenon, Quay suggests.

The National Institutes of Health were the major source of funding for this research and Quay received support from the Elsa U. Pardee Fund, a private organization (based in Midland, Michigan) that supports cancer research.

STANFORD—

To increase community attention to both speech and hearing, the Stanford Audiology Clinic of the Division of Otolaryngology and the Mid Peninsula Speech and Language Clinic of Redwood City will co-sponsor a special program on Tuesday, May 26, at 7:30 p.m.

To be held in Faber Auditorium at the Children's Hospital at Stanford, the program is offered as a public service, free of charge. It is presented in recognition of May, designated "Better Speech and Hearing Month."

Key speakers will be Dr. Holly Hosford-Dunn, director of the Stanford Audiology Clinic, and Dr. Kathryn R. Beadle, executive director of the Mid Peninsula Speech and Language Clinic and a member of the clinical faculty at Stanford School of Medicine.

They will discuss "Speech and Hearing Disorders: Identification and Treatment," after which small group discussions led by Clinic staff members will address specific questions about hearing and communication disorders.

Stanford University School of Medicine and the Speech and Language Clinic parted ways officially August 31, 1980, after 20 years of operating a state-wide program for patients with communications disorders.

The Clinic was reorganized as a private professional corporation, and continues to serve the patients of Stanford, the Palo Alto Medical Clinic, Children's Hospital at Stanford and a number of extended care facilities in northern California.

The purpose of the separation was to make the Clinic more flexible and economically efficient. Since then, its relationship with the School of Medicine has nonetheless continued as a major referral source for this type of service.

EDITORS: See related story on the high incidence of sleep-related breathing disturbances in the healthy elderly.

STANFORD—

The elderly, who comprise 15 percent of the population in this country, consume 40 percent of the sleeping pills, but surprisingly little is known about the short and long term health effects of these medications in older people.

Sleep researchers at Stanford University Medical Center are now seeking volunteers age 62 or older to participate in studies exploring the effects of sleeping pills on nocturnal physiology and their carryover daytime effects following nighttime ingestion.

The studies, which will take place beginning in July, are one component of a $3.5 million project on sleep disorders in the elderly funded by the National Institute on Aging and based at the Stanford Sleep Disorders Center.

Dr. William C. Dement, professor of Psychiatry and Behavioral Sciences and director of the Sleep Disorders Center at Stanford, is principal investigator on the project.

"It has been conclusively established that the disproportionate prescribing of sleeping medications to elderly people with insomnia lacks a clear scientific basis," says Dement.

"Nevertheless, given the prevalence and severity of insomnia complaints in the elderly, safe and effective relief is very important. We want to determine if any compounds can be used to treat sleep problems that will not have the adverse side effects we associate with most sleeping pills."

Most hypnotics, or sleeping pills commonly prescribed, are slow to be broken down and excreted by older people whose metabolism rates have slackened, explains Dement. For this reason, when taken night after night, the compounds and their breakdown products accumulate in the body, impairing daytime functioning, alertness and coordination, he says.

In fact, Dement believes that the daytime drowsiness people attribute to lack of a previous night's sleep, may actually be a delayed effect of the drug they took the night before to induce drowsiness.

-more-

But daytime drowsiness is not the only side effect associated with most sleeping medications, he warns. New evidence indicates that these hypnotics, most of which are respiratory depressants, can worsen sleep-related breathing disturbances found in almost 40 percent of the elderly.

Dement and his colleagues plan to examine the effects of new short-acting hypnotics in elderly volunteers, as well as to monitor the effects of more conventional drugs.

Volunteers, who must be 62 or older, will be screened to make sure they are not suffering from any severe sleep disturbances. In the study, they will be required to spend five consecutive days and six nights at a student dormitory on the Stanford campus set aside for sleep experiments during part of the summer.

Volunteers will take one of a variety of sleeping medications. During the night, they will be attached to monitors that measure their sleep and waking patterns, their heart rate and breathing functions. In the day, their alertness will be measured and their performance of various tasks tested.

"This is a very exciting study because of the 24-hour monitoring plan," enthuses Dement. "Sleep has always been isolated from wakefulness, and the result is a century of meaningless data. We want to correlate problems of sleep at night with those of wakefulness during the day."

This is a pilot study planned with a relatively small number of volunteers, probably 15 to 20, Dement says. In future studies, the researchers may study large numbers of people using "ambulatory" monitors the volunteers can take home.

Data from these experiments could be very significant, Dement points out. "These data may guide the use of sleeping pills in this country," he says.

Those interested in volunteering should call (415) 325-4697 of 497-6601. All volunteers must be selected by July 5 with the study to begin July 13.

STANFORD—

Dr. Allen B. Barbour has been appointed Associate University Ombudsman for the Medical Center, Stanford University President Donald Kennedy announced today, May 20.

Barbour, a clinical professor of medicine, will serve effective Sept. 1 under University Ombudsman John D. Goheen.

In the newly created position, Barbour will handle complaints and grievances for M.D candidates and all other students at the Medical School, and for residents and interns at the hospital.

"This is the first time that interns and residents have been provided with the service of an ombudsman at Stanford," said Dr. John P. Steward, associate dean for student affairs at the Medical School.

Previously, students at the Medical School were referred to the main campus for mediation service.

Faculty and staff of the Medical School will not be affected by the new arrangement and will continue to seek mediation assistance from Goheen's office, Steward said. Hospital employees, other than interns and residents, are unaffected by the restructuring, he said.

Since 1969, the ombudsman at Stanford has served as a mediator seeking to protect students, faculty and staff from injustices or abuses of discretion.

Goheen said Barbour will handle such issues as disputes by interns or residents about working hours, or complaints by medical students about the quality of a course.

The Committee on the Well-Being of Medical Students, composed of students, residents and faculty members, recommended last year that a second ombudsman with knowledge of the Medical Center was needed at Stanford.

Barbour was recommended for the appointment by a faculty-student-resident committee "and he was clearly our first choice," said Steward.

The committee acted under the direction of Lawrence G. Crowley, vice president and acting dean of the School of Medicine.

Barbour came to Stanford as an assistant professor of medicine in 1963 after 10 years in private practice in internal medicine at San Rafael. During that same decade he served on the faculty at the University of California, San Francisco, where he had graduated from medical school in 1943.

Barbour has served as chief of the Division of Ambulatory Medicine at Stanford Medical School. He organized the Stanford Diagnostic Clinic and has served as its chief since 1971.

In addition to his parttime duties as ombudsman, Barbour, who becomes a professor emeritus, said he hopes to pursue medical writing.

EDITORS: See related story on volunteers needed for study of sleep and sleeping medications in the elderly.

STANFORD—

Two out of five people above age 62 may stop breathing many times while asleep at night without even being aware of the problem, according to Stanford University sleep researchers. But these breathing disturbances, or apnea episodes, may cause fitful sleep and contribute significantly to daytime sleepiness, the researchers add.

Nearly forty percent of healthy elderly adults taking part in a one-night sleep monitoring study experienced five or more sleep-related respiratory disturbances per hour of sleep, according to results published in the current issue of *The Journal of Gerontology* by Drs. Mary Carskadon and William Dement of the Stanford Medical Center Sleep Disorders Center.

However, the sleepers all awakened during the periods of stalled breathing and recommenced normal respiration. This leads Carskadon and Dement to suggest that widespread insomnia and fragmented sleep among the elderly may be a result of apnea-induced arousal, and the disruption of sleep may be an important factor in daytime sleepiness among the elderly.

In addition to the 37.5 percent with clearly documented apnea (five or more arousals per hour of sleep), another 17 percent had "borderline" apnea, between one and five breathing stoppages and consequent arousals per hour.

Dement stresses that the study participants were healthy elderly volunteers who presented no sleep problems and had no sleep complaints. The 40 volunteers, ranging in age from 62 to 86, both men and women, were recruited from senior centers, church groups and other non-clinical sources. Some had not a single respiratory disturbance during the nighttime study while one woman topped the 200 mark, with 216 episodes, averaging about 45 arousals per hour.

The prevalence of apnea is much higher among the elderly patients with sleep complaints who seek help at the Stanford sleep disorders clinic, Dement points out. He estimates that among the 15 million people over 62 in the U.S., perhaps almost half, or seven million, suffer from sleep apnea.

-more-

STANFORD UNIVERSITY MEDICAL CENTER
News Bureau Stanford, California 94305

2-2-2

Dement is professor of Psychiatry and Behavioral Sciences and director of the Sleep Disorders Center at Stanford University Medical Center.

To Dement, this discovered high prevalence of apnea among normal elderly people adds urgency to questions about traditional insomnia therapy; sleeping pills.

Respiratory disturbances may be an added hazard for those taking sleeping pills, he says. Current evidence suggests the possibility of a potentially harmful interactive effect of sleep apnea and sleeping pills in the elderly, he notes, "which, surprisingly, has never been closely studied.

"Preliminary data have shown a worsening of sleep-related respiratory problems when sleeping pills are given," he adds. "And it is troubling," Dement continues, "that although the elderly comprise only 15 percent of this country's population they are prescribed about 40 percent of all sleeping medications.

"It seems likely that sleeping pills are actually contraindicated in the elderly since most of these medications are respiratory depressants, and may even induce sleep apnea," Dement says.

Although among females in the study there was an apparent peak of apnea among those in their seventies, among the men apnea was equally prevalent among individuals in their sixties, seventies and eighties, the researchers report.

Previous research has shown much lower incidences of apnea in middle-aged and young people, Dement says. One study of 20 people between 40 and 60 years of age found no individuals with five or more respiratory events per hour, he says, and "even in younger chronic insomniacs, the prevalence of sleep apnea syndromes probably does not exceed 10 percent."

Additional studies are needed, Dement urges. Until recently, respiratory measures had not been made in sleep studies of the elderly, he says. "Whether these events progress to total respiratory failure or are entirely benign is one question that must be addressed by future research," he adds.

STANFORD—

The Infant Sleep Apnea Clinic at Stanford University Medical Center, the only one of its kind in California, is being consolidated with the Adult Sleep Disorders Clinic, the Department of Psychiatry has announced.

"While of significant importance as a medical facility and as a source of academic research information, operation of a separate Infant Sleep Disorders Clinic unfortunately is not economically feasible," said Karl Gray, business manager for the Department of Psychiatry.

The consolidation will produce a single sleep clinic, the Stanford Sleep Disorders Clinic, which will see adult patients, and pediatric patients in consultation with the Department of Pediatrics.

In the past, many patients have been seen for apnea, a prolonged pause in respiration that can be life-threatening if undetected, particularly in infants. It is thought to be a possible cause of sudden infant death syndrome (SIDS), in which seemingly healthy infants suddently die with no apparent cause. The incidence of SIDS in the U.S. is near two to three per thousand live births, and it is the biggest killer of infants between the ages of one month and one year.

Although apnea can occur as the result of a diagnosable medical problem, such as a neurological seizure or cardiovascular disorder, most often there is no identifiable underlying cause.

Frequently, parents of apnea infants discover the condition by finding the limp, blue and breathless baby in a crib. If found immediately, the infant can be resuscitated by artificial respiration, but time is of the essence. Without breathing, an infant usually cannot survive more than several minutes without irreversible damage or death.

The condition can severely disrupt a family's life, particularly after multiple near-misses or close calls with death. Anxious parents become afraid to leave the waking or sleeping child's side for an instant and may try to watch the child 24 hours per day.

For this reason, an effective aid has been a special respiration and cardiac monitor that parents attach to the infant when they are away from the baby's side during the day, or at nighttime.

A three-pound box linked to a belt that fits around the baby's abdomen and to electrodes that sense the baby's respiration and heart rate, the monitor can be set to sound an alarm when the interval between breaths or heartbeats increases beyond a specified length.

This means that when the infant ceases breathing, the monitor rings and the alerted parents can revive the child quickly.

Once an infant progresses without incident for several months, the monitor may be discontinued. So far, among infants on the monitor followed by Stanford, no fatalities have occurred.

About 100 apnea patients were evaluated at Stanford last year. Current patients and new ones will be referred to Pediatrics, and the Sleep Disorders Clinic will assist with evaluation of these patients when appropriate.

STANFORD—

Dr. Helen Caldicott, president of Physicians for Social Responsibility (PSR), is scheduled to deliver the convocation address at Stanford University Medical School commencement exercises June 14.

Caldicott's lecture is entitled "The Medical Effects of Nuclear War." PSR is committed to study and combat the potential dangers of nuclear hostilities.

A Stanford/Midpeninsula Chapter of PSR was organized in April.

"The Medical consequences of nuclear war are so horrendous that the medical community could not adequately respond to even a limited nuclear exhange," said Barbara Paul, a spokeswoman for the local PSR group.

The organization believes that physicians as healers bear a particular responsibility to warn the public and work against the possibility of nuclear war.

Caldicott was selected in a vote of fourth year medical students.

A Boston pediatrician specializing in cystic fibrosis, Caldicott is a former Harvard Medical School faculty member who suspended her teaching and clinical activities to concentrate on anti-nuclear activities.

Caldicott studied medicine and completed her internship and residency in her native Australia. She headed the Cystic Fibrosis Clinic, Children's Hospital Medical Center in Adelaide, Australia in 1975-76.

At the ceremony, Kathy Kraus, Stanford Medical School registrar, said 83 M.D. degrees will be bestowed, including 10 diplomas earned by students who graduated in January. Last year 78 medical degrees were presented.

In addition, 27 A.M. degrees in physical therapy, 21 Ph.D., and six M.S. degress also will be given.

The Medical School ceremony is to be held at Grant Courtyard following Stanford's 90th annual commencement.

STANFORD—

If you place a box containing a live boa constrictor into a cage of monkeys, the monkeys behave in a marked and predictable way; they become agitated and wary, avoiding the box. A solitary monkey shows the same avoidance behavior when exposed to the threatening snake, but there is an important physiological difference, recently discovered by Stanford University researchers. Despite the similarity in behavior, the solitary monkey undergoes a great degree of physiological stress on exposure to the snake while the monkeys that live in the group undergo little stress at all.

This finding of Psychiatry professor Seymour Levine and his colleagues is just one of many discoveries Levine's group has made using hormone measurements as a "barometer" of the psychological state of an animal.

"In using the snake as a stress provoker, our aim is to understand the hormone responses that accompany fear and agitation," Levine explains.

What makes his research on stress unique, Levine adds, is the use of physiological measures to assess stress rather than only behavioral signs.

"What we have shown in the snake study is that association in a social group can reduce the physiological response to a potentially threatening stimulus," explains Levine. "If we had observed only the animals' behavior without looking at their hormone levels, we would not have discovered this stress-buffering aspect of social groups," he says.

The core around which Levine's research centers is stress—fear, anxiety and other factors that cause it—and adaptation to stress, or coping. His thriving colony of squirrel monkeys on the Stanford campus has provided Levine and his colleagues an excellent primate laboratory: "There are certain things of interest that you can examine only in a highly social animal like the squirrel monkey," he explains.

The discrepancy between behavior of animals and their internal physiological state has long intrigued Levine.

"Think of how many times someone has asked you how you're feeling and you respond 'just fine,' when you're actually tired, depressed, angry or stressed," he suggests. "The person who asked you often doesn't have a clue to your internal turmoil because your behavior simply doesn't reflect any of that. We are using hormone analysis to probe that hidden, internal condition," Levine says.

For many years Levine has been studying the interactions among environmental, behavioral and social factors and hormone systems. "Many people feel you can divorce the biomedical questions from the social context. I feel that's an unenlightened attitude. You have to look at the whole animal functioning in a dynamic environment," he maintains.

-more-

"In fact," comments Levine, "ours is one of a half dozen labs in the country looking at psychoendocrinology and the only major primate lab looking at behavioral and endocrine responses to social influences."

For a time Levine carried out his work with chimpanzees at the Stanford Outdoor Primate Facility on Jasper Ridge. But those large and slow-to-mature primates could provide very sparse data at best, he recalls. "They were extraordinarily expensive to maintain, difficult to handle for data collection, potentially dangerous, and the fact that we had only a relatively small number of chimps meant that our data were statistically limited," he explains.

Since the closure of that facility in 1978, Levine has focused his primate work on a 200-member squirrel monkey colony and 50 rhesus macaques.

Two major areas of interest to Levine are the emergence of mother/infant relationships (the process of attachment) and the many facets of stress-related behavior—for example, the response of infants to early stressful events such as separation from the mother; the relationship between biorhythms, including reproductive cycles, and stress; and adaptation to chronic stress, namely coping.

A recent finding from Levine's lab brings new insight into one of the most famous observations in psychology, an experiment conducted in the 1950's by Harry Harlow and colleagues at the University of Wisconsin.

Harlow and his associates demonstrated that infant monkeys have an inborn need to attach to a "caregiving" figure; this figure could even be an inanimate object, they found. Raising newborn monkeys with either a cloth surrogate "mother" or with a wire "mother" that had an attached feeding bottle, they observed that the baby monkey clung continuously to the cloth surrogate, leaving to feed on the wire surrogate only occasionally. In other words, the "contact comfort" the cloth surrogate provided was somehow more soothing to the infant than the oral gratification it learned to receive from the wire surrogate.

When Harlow removed the infant monkey from the cloth "mother," the agitated baby cried and searched for comfort, just as a young monkey does when removed from a live mother. Because of the similarity of the separation behaviors that Harlow observed, until recently psychologists assumed the attachment to an inanimate surrogate parent was as strong as that for an actual parent.

But through hormonal studies Levine and his colleagues recently showed that the infant separated from its actual mother has the telltale hormone perturbations signifying stress while the surrogate-raised infant experiences little physiological stress on separation. The attachment bond to a surrogate is simply not of the same quality as that to a real mother, the researchers conclude.

The hormones Levine and his group measure when studying stress response are produced by the adrenal glands. The adrenals, located above the kidneys, secrete hormones that help gear up many of the body's systems to deal with a stressful situation. This hormone production occurs in response to many environmental influences that are stressful, such as physical injury, pain, disease, and temperature extremes—and also in response to psychological factors such as anxiety, fear and novelty, Levine explains.

Levine's group is also examining the hormones associated with the range of sexual behaviors, and they are finding that psychological factors and social influences can profoundaly affect the reproductive system and mating behavior.

In one series of experiments they demonstrated that the combined influence of behavioral excitement and social factors was strong enough to override even the physiological biorhythm in seasonal breeders.

They conducted the experiments with squirrel monkeys, seasonal breeders that closely mingle sexually and mate only during several months of the year. At this time in the breeding cycle, males have high levels of the male hormone testesterone which plays a role in aggression and mating behavior.

The researchers grouped males together for a period, establishing a male dominance hierarchy. They then confined the males with females at a non-mating time in the breeding cycle. To their astonishment, within 24 hours of the colony formation, the males' testosterone levels rose to breeding-season norms and mating took place, culminating in fertile conception and pregnancy.

"This is a surprising result that shows us how a simple alteration in social environment can profoundly alter behavior previously thought to be tightly controlled by a basic hormone rhythm," explains Levine.

Levine's research group includes several graduate students, undergraduates, postdoctoral scholars and research associates. Their research is funded by two federal agencies, the National Institute of Mental Health and the National Institute for Children's Health and Human Development. Like many scholars engaged in social research, Levine is concerned about proposed severe federal cutbacks in funding. "It's distressing that such research may stop at a time when we are just coming up with new ideas and understanding of how the social environment can affect our internal systems—we're just learning about some of the environmental determinants of pathological conditions, the relations between stress and the emergence of illness, for instance."

"Stress has been called the 20th century scourge," says Levine. "But what is impressive is the animal's capacity to modulate and deal with stress—what we call coping," he adds.

Several years ago Levine studied coping strategy among human parachute jumpers. "When we examined the physiological response of novice parachute jumpers, every stress-response system fired," he recalls. "But by the fifth time they leapt from the plane," he notes, "there was a very dramatic drop in their physiological stress response.

"The jumper learned he could survive, the situation became predicatable to him, and he felt he had control. Even if control is only perceived rather than real, coping occurs," Levine observes.

The notions of predictability and control are central to coping, Levine and his group have learned. To examine these variables in more detail, they are now studying multiple short-term separations of infant monkeys and their mothers. They ask, if the infant learns it can predict reunion with mother, will its interim stress reaction diminish?

Dr. Christopher Coe, a long-time research associate of Levine's, describes a typical separation study. "To look at the effect of a familiar environment on a separated infant monkey, we remove the mother and leave the infant behind with other familiar adults who can care for it. Unlike an infant that is left entirely alone, the infant appears to be totally adjusted, accommodated, and able to cope with the separation. But when we measure its hormone levels, we find that the infant with familiar adults is not really coping at all—it's showing the typical signs of physiological stress."

In related studies, their research has focused on how other variables such as novelty and familiarity, affect the separation response. "We have tried to isolate the dimension of familiarity from the dimension of contact comfort," explains Coe. "We want to know to what degree is the physical contact with another monkey essential compared to just being in a familiar place, which, in a sense, makes the situation predictable."

Seeing the mother or other monkeys during a separation is not very helpful, Coe reports. In fact, if the mother and baby are separated and allowed to see one another, it's an extremely frustrating and negative situation. "We have found this is one of the most stressful types of separation. It's actually better to separate the infant totally, where it's out of sight and out of mind," Coe says.

In future studies, the researchers will add in the variable of unpredictability, by having separations of different lengths, for instance. "We want to see if they adapt as readily," Coe says.

One ultimate aim, says Levine, is to look at "the long-term consequences of traumatic or stressful experiences during infancy. And, of course, by looking at a primate like the squirrel monkey, which shows a strong attachment relationship, we hope to gain insight into these processes in humans," he adds.

The young monkeys go from mother-infant studies to puberty studies, and then long-term consequences, three years, five years away. Since the monkeys reach puberty at three, Levine's lab is just now entering the puberty phase of study. It's becoming a very exciting, important time in their research program, Coe and Levine agree.

STANFORD—

Children entering the Hospital's inpatient Pediatrics unit these days are greeted with, "Let's try to find a choo-choo train," or "Let's count how many balloons there are."

That's how they're led to discover the artwork of Nancy Turver, a technician in Stanford's lab who has made the Peds walls come alive with brightly colored pictures, all tailored to a young child's taste for fun.

Besides the train and balloons, Turver has adorned the unit with an apple tree, a cat, a cricket, a yellow school bus, a toy soldier, a nineteen-foot rainbow, a sailboat, a snowflake, a pick-up truck, a spinning top, a Jack-in-the-Box, the sun, some birds, kites, stripes, snow geese and more.

Members of the Pediatrics staff, says Turver, have found the decorations a wonderful supplement to their patients' orientation. It makes the parents happier too, she says. "It sort of shows that somebody really cares about the kids."

Turver, who works 20 hours a week in the Hospital while aiming for a full-time career as an artist, first broached the idea with Jill Greenberg, regional operations manager for Pediatrics. Play therapist Betty Lovelace, clinical nursing coordinator Alice Morrow, Greenberg and others had been toying for some time with a plan to create a more child-like atmosphere for the unit. So Turver, after presenting her drawings, was welcomed aboard.

"At first it was sort of an experiment," she recalls. But the project blossomed as more and more children showed delight in their new surroundings.

Wallpaper, explains Turver, is often out of the question for hospital rooms because of the difficulty involved in cleaning. But her paints will present no such problem, remaining intact "for a long time."

Turver is now in the process of painting window scenes in some of the windowless patient rooms of the unit. And as a spin-off from the project, her wall graphics have been transposed into coloring books, now available at the Hospital's gift shop for $1.00 each.

Proceeds from the book, entitled *All Aboard for Good Health* (with the choo-choo featured on the cover), will be funneled back to the Pediatrics unit. The book will also be given to children hospitalized on the unit, says Greenberg.

STANFORD—

Several Peninsula women have called Stanford University Medical Center in recent weeks to inquire about telephone calls from a man allegedly conducting a survey for Stanford on birth control methods, toxic shock syndrome, and other subjects with sexual overtones.

A Medical Center News Bureau survey shows no study of this nature being conducted by Medical Center researchers; women should be aware that the male caller has no official connection with Stanford.

The phone imposter surfaced in recent months with "nuisance" calls to several women, many of them in the Pacifica area of San Mateo County. The women became suspicious when he asked numerous questions about their sexual patterns and practices.

Stanford Medical Center officials became aware of the problem when women called to verify authenticity of the survey.

According to the women, the caller identifies himself as a researcher with Stanford Medical Center and, occasionally, with Planned Parenthood.

Planned Parenthood officials contacted by Stanford similarly deny having any connection with the telephone survey. They stress that Planned Parenthood also has no research survey under way, and would not conduct a survey on birth control methods by telephone.

STANFORD—

In the hours following Mary Gohlke's March 9 heart-lung transplant, things were hectic for Stanford's cardiovascular intensive care unit.

One overriding qualification for an intensive care nurse, says Audrey Covner, R.N., Gohlke's first post-operative nurse, is, "You have to know when to sweat." This was especially true on that day.

Security guards surrounded the unit, reports Tina Freedman, R.N., another of the first nurses to care for Mrs. Gohlke during her eight weeks' stay in the unit. "It was kind of funny the way they wanted to see the nurses' I.D.'s the first day," she recalls.

But after the initial commotion subsided, those close to the case agree that little distinguished it—in terms of nursing care—from the 20 to 25 simultaneous cases they had to deal with in the north intensive care unit (NICU).

Besides transplants, the types of acute cases handled on the unit include coronary bypass surgery; heart valve replacements; repair of congenital heart defects; and aneurysms. (Other intensive care patients are cared for in the medical and surgical intensive care units.)

Since every part of the body can be affected by activity in the heart, cardiovascular intensive care nurses must have a wealth of physiological information.

"People are still amazed at how much nurses know," says Covner, who followed Gohlke on the night shift through her entire stay in the unit.

"We have to know what we're doing; we're the ones who are constantly with the patients."

Brenda Smith, R.N., acting clinical nursing coordinator of the unit, explains that each nurse is assigned to one patient's bedside for an eight-hour shift. Except for a half-hour lunch and two 15 minute breaks, she is present to observe fluctuations in the patient's condition, record and analyze data; and monitor stability.

However, like in any intensive care unit, NICU patients have a potential for sudden instability at all times. Therefore, says Kit Laird, R.N., another night shifter, "Our nurses can do anything a first-year intern could do in an emergency. We are trained to do whatever is necessary to save a patient's life, until the doctor arrives."

According to Laird, NICU nurses must be able to judge the appropriateness of specific heart rhythms for particular patients. They must be attuned to virtually all the bodily patterns of their patients, in order to manipulate both drugs and machinery for desired results—in blood pressure, for instance.

Since nurses are legally responsible for any drug they administer, they must constantly assess physicians' orders and doses given. This is especially crucial in an intensive care setting, where medications tend to be the most powerful.

In a sense it's like being a computer, says Patti Tharp, R.N., a day-shifter, the way an NICU nurse must correlate information and come up with an immediate plan of action during a crisis.

This type of activity, all agree, becomes routine—almost second nature to those with experience. Especially since cardiovascular nursing is a real specialty, adds Tharp, where similar cases are seen repeatedly.

-more-

NICU nurses must, moreover, understand the *why* of what happens to their patients, all of whom just had open-heart surgery.

In a nutshell, the secret of the NICU nurse? "We are just assertive, intelligent women and men," says Tharp.

It seems inevitable that intensive care nursing entail stress as well as satisfaction. Why would a nurse choose such a high-power specialty?

Smith explains, "ICU nurses seem to like the high activity level. Similar to nurses in the Emergency Room, they like to get right in there, do something important, and see the results quickly. They're concerned with short-range goals, primarily."

British-bred Freedman corroborates the statement, confessing that she prefers the acute situations—the short-term crises—to the transplant cases, who commonly remain in the unit for a month, long after their crisis period has passed.

"It's more demanding to be an ICU nurse," she contends. "You have more responsibility, and there are many technical aspects to the work." ICU nurses, she says, always seemed to her more knowledgeable than other nurses. So having chosen the nursing profession, she decided to shoot for its stars.

Tharp, who worked closely with Charles Walker, Stanford's second heart-lung recipient, concurs.

"I like the high pace, the recognition from my colleagues, and the greater respect and trust I receive as an ICU nurse."

But while Tharp agrees that transplant cases are really a separate part of ICU nursing, she enjoys the educational role they demand of her. "Transplant patients are really shooting for quality versus quantity of life, and they know that," she says.

As for life expectancy, 63 percent of Stanford heart transplant patients now live one year after surgery; 40 percent live five years. The longest Stanford survivor was transplanted in January, 1970.

"We must teach the patients to live with this and become self-sufficient," continues Tharp. "We try to help them get back into the flow of life."

Adds Laird, who became fascinated with intensive care nursing while working her way through school as an ICU aide, "The idea for all of our patients is that they'll be going back to normal lives, and that we're only playing a small part. We must keep this in perspective ourselves, and help our patients to remember it, in order to keep them sighted on their goals."

Covner, impressed by Stanford's nursing staff when she first arrived a little more than a year ago, recalls, "I'll never forget when my first patient (cardiac) arrested on me. I pushed my emergency code button, and suddenly there were lots of people in the room to help. . . . It works here because of the team work."

When an emergency arises, she explains, the nurses cover for one another, often working overtime. If one patient requires two nurses, he gets them.

NICU nurses' schedules are set for a month at a time, says Smith. There are a total of about 130 full and part-time nurses currently working on the 25-bed NICU. Collectively they must cover days, evenings and nights—including weekends.

Generally, says Smith, a nurse has the same assignment for two days in a row. But if she elects, she may continue to follow a particular case. For transplants and other long-term patients, one nurse becomes the "primary," as Covner was for Mrs. Gohlke.

The primary nurse is responsible for coordinating her patient's care. Focusing exclusively on one case, she is in a position to lead the team of health care professionals involved. Besides physicians and associate nurses, this may include social workers, chaplains, nursing assistants, physical and occupational therapists, and dieticians.

Her role is important, for physicians and residents are often tied up in the Operating Room. NICU's sole supplier of patients. Six to eight patients arrive from the O.R. every day (except on weekends). While residents are officially on call at night, a nurse is often the one to make an urgent, life-saving decision.

For every two rooms in the four-year-old NICU (which was previously combined with the Hospital's other intensive care units), there is one "floating nurse"—someone assigned to go in and out, back and forth, all the time. So essentially, each room has about one-and-a-half nurses.

Patients are usually doubled up in a room, except for the transplant cases. These, explains Laird, must be isolated, since the drugs used to lower risk of rejection of foreign tissue (called immunosuppressants) also lower resistance to infection.

Even the nurses, she says, for at least a week or two after surgery, must wear gown, gloves, mask and booties. (They eventually cut down to a mask and booties.) And transplant patients' rooms include a special "anteroom" for putting on these costumes. One door leads to the outside and one to the patient; the two must not be opened at once.

Unlike many other hospital units, the NICU has no central monitoring equipment. Instead, there is monitoring machinery in every patient room. This, say the nurses, facilitates primary nursing care, and is not only safer but makes patients feel safer.

Patients do, however, become accustomed to having one person by their sides at all times, and many may have difficulty making the transition to a regular ward.

In order to ease the impact of transferring, NICU nurses train patients to know their own medications and warning signals. Says Freedman, "Transplant patients who are successful are extremely well-informed."

For transplants, a weaning procedure called "self-relief" may be used, whereby the patient is eventually allowed to be alone in his room for designated periods of time, always within reach of immediate help. Besides the patient's physical condition, the use of this option depends largely on his attitude and/or degree of fear. Charles Walker, reports Tharp, did quite well with his free time while on the unit.

The admiration is mutual. Commenting recently on his perception of the unit, Walker indicated that the NICU nurses could not have been more supportive of both him and his mother. They have given, he said, so much—including such tangibles as pots and pans for setting up house nearby, and their own home phone numbers for ready emotional stroking.

Explains Tharp, "Transplant patients and their families really need lots of psychological support. They have to deal with the fact that someone else's organs are in their body, and that this gives them a second chance to live."

On an emotional level, all the nurses agree that it's important with any transplant case to keep the issues of donor and recipient separate. This is for the good of both families, says Tharp, each of whom needs to resolve something different.

"Of course we couldn't do without the donors," says Laird. "There are patients who have been accepted as transplant recipients but who die before a donor becomes available."

And if a transplant does take place, she continues, there is often much sensitivity regarding the donor family—especially when the latter puts an emotional strain on the recipient, viewing his progress as its investment.

"Donors' families," says Laird, "should just know that they've given a very special gift—the gift of love, the gift of life—but there is no string on that gift.

"As a very articulate transplant recipient once said to me, 'You have to love the whole world better, not just the person who gave you your new heart, because that would cheapen the gift. It's bigger than that. Every day has to count and be special to you.' "

More than other patients on the unit, adds Tharp, transplant recipients develop close ties with their nurses. "They will talk with us about sexual activity, exercise, diet, whatever."

And if you follow a patient and get to know his family, says Covner, you're bound to feel some emotional tie. "Even an ice cube would melt a little."

This requires an important balance of any nurse. Explains Laird, "It's not sympathy, but empathy that we feel and they need. You know there will be an end point to the relationship: whether the patient dies, or gets better and moves on." There are nurses, though, who continue such friendships—some have even attended their former patients' funerals.

Since intensive care patients often have trouble doing ordinary, every-day things for themselves, says Smith, the nurse's job can at times be tedious. But even routine chores—such as combing or washing a patient's hair—are really quite important, says Covner, from the patient's point of view.

Moreover, whether anything dramatic occurs or not, adds Laird, "You know that you've mattered, when you've been at a patient's bedside for eight hours."

Agrees Freedman, "At that point you know what's going on with that patient better than anyone." She continues, "We would like more recognition for what we do."

Freedman's concern for the image of nursing is echoed by the others. The profession itself, they feel, has come a long way, but the public's conception of it has not.

Nurses, says Tharp, are still very much stereotyped as the "handmaidens of doctors." And they would like to emerge from the "bedpan era" in the public eye.

NICU nurses, says Covner, are a real liaison between patients and physicians. "The doctors depend on what we tell them. I really feel the doctors respect the nurses on our unit."

Any new nurse hired at Stanford must participate in an in-depth orientation, with classes given by the educational coordinators.

Then, says Smith, all nurses assigned to an intensive care unit must take a five-day critical care course, whether or not they have previous experience in an ICU. The course covers diseases, treatment and nursing care guidelines. "It really covers the gamut of what you usually see in an ICU."

In addition to this, many one, two or three-day workshops are offered on such topics as respiratory treatment, pediatrics, and advanced critical care. According to Smith, there's a wealth of choice as to what a nurse can do, and the specialties she may develop.

Only recently, she continues, has her unit begun to hire some new nursing graduates with no ICU experience. Those with experience, she says, are simply harder to find nowadays. Besides the nursing shortage being felt nationwide, Stanford faces the handicap of its overly expensive location.

"When we saw inflation go up," says Smith, "we saw applications go down. Many people prefer to stay put, rather than relocate and risk lots of money in the Bay Area."

But according to Smith and the other nurses interviewed, the new grads—by virtue of real hard work—have done quite well. Upon arrival at the unit, they are placed on "buddy time," whereby an experienced nurse helps them out and evaluates them periodically. Stresses Laird, "You're never left alone when you're first starting or learning."

A new hire always begins on the night shift. Eventually she participates in the unit's system of month-by-month rotation. Some lucky nurses with seniority privileges are assigned as permanent day-shifters.

And then there are those rare few who actually choose the night shift. Covner and Laird both did. Explains Covner, "A lot of my friends are not nurses. So this way I can sleep during the day, and do my socializing in the evenings before work."

A somewhat different evening event is the pre-operation course for patients and family members conducted by NICU nurses on a regular basis. The program includes a short slide show, a short run-down on what is likely to happen after surgery, and a question-and-answer period. Patients participate on the evening prior to their scheduled surgery.

more

For child patients, the nurses make a special visit before surgery, carrying a toy doll equipped with all the body's organs. And when visiting pre-transplant patients, they bring a chart for illustration.

The idea, both pre- and post-operation, is to help the patients not to be frightened, and to reassure them whenever possible. Says Covner, "We're very honest with our patients. I think we're really patient advocates."

"The hardest thing for me," says Freedman, "when it looks hopeless for a patient, is dealing with the family—watching people watch their loved ones die.

"There are often things you can do," she continues, "to prolong life for the short-range: for one day, perhaps. But with all the anguish involved in this 'hanging on' period, you sometimes wonder if it's worth it."

Of course, nurses don't set the policy. Whatever the attending physician and the family decide, they must adjust to.

"And if they do decide to withdraw treatment at some point," says Tharp, "that's also very difficult for a nurse. Because you usually feel so much in control of things, technically. When activity is stopped you feel weird, like there's nothing else you can do."

It's important, she continues, for nurses to go through their own mourning process when a patient dies. "Everyone probably does this in her own way. I find I always think of the patients who have made it. Also," she adds, "supporting the family members is hard, but they can often support you back too."

Every procedure performed on the NICU is documented by what's known as a patient-care plan. Based on her first-hand experience with Mrs. Gohlke, Covner has written such a plan for heart-lung transplant patients, which is now in use on the unit. It was edited by Dr. Bruce Reitz, Gohlke's primary physician and head of the cardiovascular surgical team which performed the transplants.

"The plan will need revision as time goes by," explains Covner. "What may have worked with Mary, may not work for everyone."

Covner is now in the process of writing an article on the nursing care of heart-lung transplant patients, also to be edited by Reitz, which she hopes to have published.

She contends that other than certain new technical aspects, the experience was similar to following any other heart transplant patient.

Notes Smith, "We did not really treat Mary as a special patient. She was seen as one of our patients, all of whom receive the best nursing care possible. In that respect there was no difference."

Naturally, though, there was more a sense of the unpredictable with Mrs. Gohlke. "Nobody quite knew what to expect," says Freedman.

And the newness of the surgery did make the case stand apart. Mrs. Gohlke did, after all, have lungs as well as heart replaced. It was important, says Smith, for the nurses involved to have had extensive experience with many other kinds of cases, resources of knowledge to incorporate in handling this one.

Note to Editors: Symposium programs and individual papers of interest available upon request.

STANFORD—

The progress made in understanding and treating that disabling, complex disease, psoriasis, will be the main focus at the Third International Symposium on Psoriasis, to be held at Stanford University Medical Center July 13 through the 17 in the Fairchild Auditorium.

Six to seven million Americans have psoriasis. The disease, which results in thick, red, silvery-scaled patches on the skin, has no cure, and its cause is unknown. In some cases, the disease cannot even be controlled. It strikes both sexes, all ages and almost all races, everywhere in the world.

Researchers throughout the world have been working to find the cause of psoriasis, whose hallmark is uncontrolled and accelerated growth of the skin cells. So many things could be responsible for the condition that the work requires the collaboration of scientists of many different disciplines—dermatologists, cell biologists, cancer specialists, immunologists, biochemists, geneticists, virologists, and pharmacologists.

Reflecting the wide range of disciplines involved, the program is very diverse, covering everthing from the basic pathogenetic aspects of psoriasis to appraisals of the various therapies for the disease.

Both genetic and environmental factors may contribute to psoriasis. In one-third of the families of psoriasis patients, other family members also develop the disease, suggesting a genetic predisposition. Various environmental factors, such as injury to the skin, infection, or drug eruption, provoke or aggravate the condition.

Doctors hope that with a better understanding of the disease will come the development of specific treatments for the different forms of psoriasis.

Today, no completely satisfactory method of treatment exists. But a variety of procedures—ultraviolet light, coal tar, steroids, vitamin A compounds (retinoids), and anti-cancer drugs (in the most severe cases)—can cause regression or modification of the scaly patches. Their actions will be extensively discussed.

The press is cordially invited to attend the symposium. If you plan to come, please fill out the form below and return to:

STANFORD—

The Department of Anesthesia recently held its annual farewell dinner to honor departing housestaff, at the World Trade Club in San Francisco. Three special awards were presented at the event.

For exceptional skill and dedication to patient care, as well as clinical research resulting in publications and presentations at national meetings, Douglas Merrill, M.D., received the Robert D. Dripps Memorial Award. In July, Dr. Merrill will begin a two-year fellowship in neuroanesthesia research at the Mayo Clinic.

The Dripps Award is named for one of the distinguished pioneers in anesthesia, who was professor and chairman of the Department of Anesthesia at the University of Pennsylvania for 23 years. It was donated by the Janssen Pharmaceutical Company to honor the outstanding house officer in Anesthesia at Stanford for 1981.

The Faculty Teaching Award is given by the graduating housestaff to the faculty member who has made the most outstanding contribution to their education during the past year. The 1981 recipient was Donald Stanski, M.D., assistant professor of anesthesia and medicine (Clinical Pharmacology), who is nationally known for his studies of the pharmacokinetics and pharmacodynamics of thiopental and d-tubocurarine.

The Ellis N. Cohen Achievement Award, named for Stanford's distinguished emeritus professor of anesthesia, is to honor a faculty member whose accomplishments and contributions to the field during the past year best exemplify the highest standards of excellence. This year's recipient was Edgar Yhap, M.D., associate professor of clinical anesthesia and chief of the General Anesthesia Services at Stanford University Hospital.

Earlier this year, Dr. Yhap was awarded the Legion of Merit by the Surgeon General of the United States Army at Letterman General Hospital, to acknowledge his exceptional contributions to military medicine for 20 years.

Although at Stanford for only one year, Dr. Yhap has had a remarkable impact on the teaching, clinical care and administration of the anesthesia services at the Hospital, according to department chairman C. Philip Larson, Jr., M.D.

STANFORD—

Just seconds before a giant jetliner is to touch down on the runway, the pilot suffers a massive heart attack.

The co-pilot is trained and poised to take over within seconds of such an emergency, but this time, the ground is less than a second away, and the plane dives fatally. The resulting crash kills 450 persons.

Although the scene is fictitious, it punctuates the unique concern over monitoring commercial pilot health. There are few, if any, comparable situations where a single individual holds the lives of so many persons directly in his or her hands.

Consequently the retirement age for pilots has been set at 60, lower than for most jobs.

But the need for a mandatory retirement age is under review by Congress and was studied recently in an Institute of Medicine study. Entitled "Airline Pilot Age, Health and Performance," the March 1981 report concluded that while physical and neurological functions do decline with age, "usually no single age merges as a point of sharp decline in function."

Dr. Donald Harrison, chief of cardiology at the Stanford University Medical Center and a member of the study committee, said in a recent interview that neither an early retirement age nor more frequent health exams are necessary to make flying even safer than it already is.

Rather, Harrison believes that less frequent—but more comprehensive—physical exams could become the core of improved health monitoring for the nation's airline pilots, whom he believes because of pressure might not fulfill the image of robust good health often associated with the profession.

What Harrison suggests is that when pilots reach about age 50, they should be categorized, based on medical history, past physical exams, and laboratory studies as either high or low health risks for coronary disease.

Risk factors such as cigarette smoking, high blood pressure or high cholestorol could place the pilot in the high risk category. Since these elements are at least partially controllable through healthful living, the pilot wishing to remain in the cockpit would be motivated to modify his lifestyle, Harrison believes.

-more-

"Until age 50 there should be lots of education in these people about what cardiovascular risk factors mean.

"After age 50," Harrison continued, "those persons who fell in the higher ranges of risk factor profiling, would then be required to do some of the more technological testing exercies, such as stress ECG.

"What we're proposing is a cascade of tests.

'If a pilot fails one test, he would be given another test to check the validity, since the sensitivity and specificity of the tests are not always conclusive. Of course if he or she passed the first tests, the additional tests need not be ordered."

After about age 60, Harrison suggests that the burden of proof be shifted to the pilot, who would then be required to pass a battery of sophisticated tests as evidence that he or she was in fact fit enough to fly.

Although there is no evidence that 60 is a significant age for physical or neurological deterioration, Harrison believes that all pilots be required to stop flying commercially after age 70.

"At that point," he said, " In most there clearly is deterioration of physical, psychological and neurological function, and no one on the committee suggested that persons be allowed to pilot airliners after that age."

The study, prepared in response to a 1979 law calling for a study of the mandatory retirement law, was not intended as an indictment of flying safety.

"Flying is damn safe now. We just feel that everything possible should be done to make it safer," Harrison said.

"Since we have the means to technologically improve our testing, we ought to go all the way and make it safer," he added.

Since the current physical exams were established in the 1950s, new more sensitive and accurate tests have become available. An example is coronary angiography, a procedure which enables physicians to examine the interior of arteries by injecting dye and then x-raying the vessels.

State of the art tests can be expensive, and because dyes are injected into the blood vessels of the heart, they involve a risk. Therefore, Harrison believes they should only be given to high risk pilots, including all those older than about 60. He says that a coronary angiography should only be used after noninvasive tests such as treadmills or the clinical history, for example, suggest a cardiac or related condition.

3-3-3

Currently the FAA requires physical exams yearly, but Harrison believes that a test every two years is sufficient for pilots without evidence of a health problem up to age 50. But he cautions that such biennial exams should be comprehensive and standardized.

As for younger pilots, Harrison notes that they are selected for their good health, and there is reason to believe that they are lower than average risk for disease.

But Harrison cautions that there is little evidence either way to suggest that older pilots are unusually good health risks.

"We believed as a committee that as they approached the 50s or so that there was certainly no evidence to point to them having low risks. If anything they were at least at the average risk.

"They are highly stressed. They're switching a lot of time zones. They are away from home a good deal. Their diet is not always very well regulated. A lot of them don't exercise very much.

"So even if they were selected as a low risk group, they frequently are now into a high risk profile."

"But the problem with all of this is that there has been no documentation," Harrison said.

The cardiologist noted that more studies about pilot health are needed, but these are difficult to obtain because of the reluctance of pilots to discuss health problems which could force them to lose their flight status.

An indication of the fear of reporting medical problems, Harrison believes, is reflected in the statistics involving heart attacks by pilots in flight.

Between 1961 and 1968, 11 pilots suffered heart attacks in-flights, although no fatalities resulted. In eight cases the pilot died. Harrison notes that this is far beyond the usual 20 percent fatality rate for heart attacks, indicating two possibilities:

Either the stress conditions during flight are so severe that otherwise routine heart attacks were intensified, or additional unreported heart attacks occurred in flight.

The study notes that the potential for heart attacks is greatest at times of stress, which in the cockpit are likeliest to occur during take-off, landing or during an emergency.

"If you have one message that comes through our whole report," Harrison said, "it's that we need to know more about the psychological, physiological, the stress responses, the cardiovascular and endocrine functions as it changes in pilots."

While medical experts, the government and pilots are working to evaluate the health of pilots, technological developments involving aircraft are working to make flying safer, perhaps even reducing the role of the pilot. Onboard computers, Harrison notes, are playing an increasingly larger role in the actual flying of airplanes.

Note to Editors: The competitive version of the Para-Bike, one of its designers, Doug Schwandt; its record-setting rider, Asher Williams; and a primary sponsor, the Telephone Pioneers of America will be available to meet with the press on Thursday, June 18. They will be at the Rehabilitative Engineering Research and Development Center at the Palo Alto Veterans Administration Center, Bldg. 51, 3801 Miranda Avenue, Palo Alto, at 10:30 a.m. For further information on the press conference, contact Mr. Bob Brown, press relations manager at Pacific Telephone, (408) 491-6346.

Also, a videotape of the International Human-Powered Vehicle Association Championships is available from which tapes can be made. Doug Schwandt can be reached at (415)493-5000, ext. 4473.

STANFORD—

People clapped when Asher Williams pedaled by last month—even before he set a world's record.

Asher, whose legs were paralyzed in a diving accident last summer, was racing in the International Human-Powered Vehicle Association Championships.

Snuggled under a tear-shaped fairing to reduce the air drag, he hand pedaled himself to speeds of 25 miles per hour, just edging out Marshall Smith who reached 24 miles per hour.

Although racing foot-powered bikes reach speeds more than twice that great, this is the fastest ever clocked for a hand-powered bicycle. It is considerably faster than the speed of the common variety bicyclist.

Williams and Smith were pumping the competitive model of the Para-Bike, a first-of-its-kind bicycle for paraplegics that is being developed at the Rehabilitative Engineering Research and Development (RERanD) Center at the Palo Alto Veterans Administration Medical Center.

In addition to his speed record at the Pomona (CA) racetrack, Williams went a distance of 3.6 miles around the track, matching himself against more than 30 foot-powered bikes.

In this International Year of the Disabled Person, Williams and Smith were breaking away.

Smith is an administrator of the International Year for the province of British Columbia. The 54-year-old Canadian had biked all his life until an accident two years ago left his legs paralyzed. Williams, 21, was a West Point Cadet—running, swimming, lifting weights every day—when he dived into a too-shallow pond last July and damaged his spinal cord.

Both, as are many paraplegics, are still avidly interested in sports, wanting to take part in the many recreations available to the able-bodied, if possible. The Para-Bike gives them the chance to feel the exhilaration of biking again, as well as provides an excellent aerobic exercise.

Hand-pedaled tricycles, but not bicycles, have been around for years for persons without the use of their legs, says Doug Schwandt, rehabilitation engineer at the Center.

But trikes don't provide the same free, flying feeling bikes do, he says.

-more-

Schwandt and Candy Mintz were challenged by the idea of designing such a bike a year and a half ago while working for masters degrees in Stanford University's Design Division, under the guidance of professors Larry Leifer and Philip Barkan. Under the sponsorship of the RERanD center, they worked closely with Leifer, director of the Center, and Peter Axelson, a Center biomedical engineer. Axelson, who is himself a parapiegic, had the idea of developing an alternative cycle for the disabled. He is a great proponent of the development of recreational equipment for the disabled; he designed the ARROYA, a downhill skiing sled for paraplegics.

They created a bike of a different order: the cyclist rides low and the pedals are high. The cyclist, equipped with specially padded skateboarding gloves and low to the ground sports-car style, suspends his legs in cushioned slings, which can be quickly released. Instead of handlebars, the rider uses a hand-cranked chain wheel and chain linked to the front wheel to both propel and steer himself.

To stop, the rider merely back pedals.

Because the rider is so low the ground, there is a feeling of speed on the Para-Bike, Schwandt says, and a sensation of floating.

For beginners, an extra option and precaution is a heavy-duty rollerskate wheel mounted on the frame on either side of the rider ready to touch down should he begin to fall.

When expertness is mastered—Schwandt says that just as in learning to ride a regular bike, one must learn to balance the Para-Bike—the rollerskate wheel, which tends to limit the turning radius, can be cast off.

The version that Williams and Smith rode last month in Pomona is the 2nd prototype. It was built by Peter Johnson of Palo Alto, who has designed, built and races his own "streamline" cycle. Fred Tatch of Eugene, Oregon, designed and built the fairing.

The designers decided to concentrate on making a racing bike because the demands of design made for a competitive model would likely result in faster development of a purely recreational one.

The Sierra Pacific, George S. Ladd and John I. Sabin chapters of the Telephone Pioneers of America, the service organization of the Bell Telephone Co., helped sponsor the competitive version of the Para-Bike. As one way to make the Para-Bike available to disabled persons as soon as possible, these Northern California chapters hope to interest other chapters in the U.S and Canada to help fund the construction of Para-Bikes to be used in their local areas.

Schwandt says that several persons have shown interest in producing the Para-Bike. He estimates that it will cost approximately $1000 to make.

Already on Schwandt's drawing board are plans for a tandem bike, for an able-bodied person and a paraplegic. He hopes to design it such that the disabled person could ride it alone, if he wanted.

Schwandt says he thinks that the racing version of the Para-Bike can reach speeds of 30 miles per hour. But once the fairing is removed, it becomes a more mild-mannered means of recreation. Schwandt and Williams can be glimpsed some days pedaling around in the bike lanes of Stanford and Palo Alto.

STANFORD—

In the pitched battle to combat cancer, an old strategy—that of killing cancer cells with heat—is being dusted off and the tactics are being refined.

And while it appears that heat won't be the ultimate weapon, researchers have hopes that it will at least be a delaying tactic in situations where other methods have failed. Also, they've good evidence that this plan of attack—called hyperthermia—may make standard radiation and chemotherapy treatments more devastating to the tumor.

At Stanford and several other medical centers, researchers are beaming high-frequency sound waves (ultrasound) or microwaves at tumors in the hope that the great heat they generate will stop the tumors short and shrink them.

Other researchers are experimenting with radio-frequency waves. Some are heating the entire body—not just the tumor—with hot wax baths, hot water suits, or heat exchangers with dialysis-type shunts that raise the temperature of the entire body.

At Stanford, so far the focus has been on ultrasonic heat therapy. Dr. George Hahn, associate professor in the division of radiology, began testing the effect of heat on cancer cells in the laboratory in the early '70's.

Later, the treatment was tried on patients and found to cause some superficial tumors to dwindle, if only temporarily, says Dr. Jane Marmor, assistant professor of radiology. Tumors—heated to lethal temperatures of 110 degrees or more— shrunk in 43 percent of the 45 patients that she treated with ultrasound.

One of the limitations of the technique has been that only tumors no deeper than three cm—or just a little more than an inch—below the surface of the skin could be superheated because the ultrasound waves penetrated poorly.

Now, Douglas W. Pounds, a physicist in the department of radiology, has developed a machine that is able to reach some deep-seated tumors.

Marmor, Pounds, Hahn, Malcolm A. Bagshaw, chairman of the department of radiology, and Peter Fessencen, assisstant professor of radiology, began experimentally treating patients this year.

The device has several ultrasonic beams instead of one. At first, the beams are wide-spread and of low intensity, but later converge on target with considerable strength, thus sparing the normal tissues through which they must pass.

Previously inaccessible tumors in the stomach, pelvis and extremities can be treated, says Marmor. But she qualifies that not all tumor types will be suitable targets. Ultrasound won't be able to reach lung, brain, or abdominal tumors lying behind air-filled organs because air and bone reflect the ultrasound beams.

-more-

Marmor says much has to be learned before hyperthermia becomes a medaled member of the armamentarium against cancer.

"My guess is that hyperthermia will prove helpful, but it won't, by itself, be a cure for cancer," she says. "I doubt it will replace the standard modalities, which are surgery, radiation and chemotherapy. Rather, I believe it will be a good adjunct therapy."

One of the obstacles to evaluating how effective hyperthermia can be, Marmor says, is that so little is known about its dosimetry—how much heat to apply, for how long and by which means. Neither is it known how many treatments are enough.

That's what she and her colleagues at Stanford are trying to determine. She stresses that such dosimetry studies must be carefully controlled before it can really be determined how effective hyperthermia is against cancer. Hyperthermia equipment is already on the market, but Marmor is skeptical of its effectiveness.

In research centers, hyperthermia is usually used as a last resort—when standard treatments have failed—because it is still experimental.

Marmor's patients had incurable, spreading cancer unable to be controlled with other treatments; some had received all the radiation they could tolerate.

Marmor predicts the hyperthermia treatments may be given in the future along with the radiation. She and Hahn found that in 7 of 15 patients with multiple, superficial tumors treated with either radiation or radiation plus ultrasound, those tumors receiving both radiation and ultrasound regressed more.

In experimental model systems, hyperthermia also increased the effect of cancer drugs, Marmor says and so may prove to be a valuable companion treatment to chemotherapy, too.

Just how hyperthermia works is not known. Some researches believe that tumors are particularly susceptible to heat because they have a scantly blood supply and can't efficiently export the excess heat. Others suspect that the DNA and protein repair mechanisms of tumor cells aren't up to par.

In the early '70's, Hahn found that nutritionally-deprived cells such as tumor cells are especially sensitive to heat. His later work suggests that heat deals a blow to the workings of the cell membrane.

The side effects of hyperthermia are relatively mild and short-term compared with those of surgery, radiation treatment, or chemotherapy. But, of course, these three are also more effective than the heat therapy. With ultrasound hyperthermia, Marmor says, patients sometimes feel pain and a few develop skin blisters in the treated area, especially if it is near bone.

It will be years before the jury comes in on just how effective and useful hyperthermia is, Marmor says, but from what's been seen so far, the trials should definitely go on.

STANFORD—

Charles Walker walked out of Stanford University Hospital this morning (Tuesday, June 16), 48 days after he received a heart-lung transplant.

The 30-year-old, bearded Walker, who had been born with a heart defect, seemed all good cheer, joking and smiling.

Before the operation, walking was a chore for him; he was out of breath within minutes due to his damaged lungs. Although he still is not ready for a hearty hike, he can now stroll around the Hospital and out of it with ease.

The past two weekends Walker, who has recovered from his operation free of any major problems, ventured out into the world again, dining at local resturants, and trying out the sunbathing at the pool of the apartment his mother is renting.

Mr. Walker received the fifth heart-lung transplant in the world on May 1. His lungs had become damaged as a result of his congental heart defect. Although he has repeatedly been hospitalized since birth, his condition worsened almost three years ago, and he was forced to quit work. Eventually, he was told that his only hope was the experimental heart-lung transplant operation.

Mr. Walker will live in the Stanford area with his mother, June Spangenberg, for the next two or three months. Doctors will further adjust the doses of the medications he must take the rest of his life, and keep checking for any signs of rejection of his new heart and lungs.

Unless controlled by drugs, the body marshals its defense, or immune, system against the transplanted organs, which it registers as foreign agents. The greatest threat of rejection is in the first three months after the operation, but it it always there. Although it is not uncommon for transplant patients to have a bout with rejection, Walker has had no problems.

When he gets the okay from doctors, he plans to return to his home in Binghamton, N.Y., and his poodle Teddy, who has a passion for chocolate malt balls. Eventually, he plans to go back to work as a mortician.

-more-

He has no definite plans for this summer, other than to keep exercising to build up his strength and stamina. The nurses of Stanford's intensive care unit, where Walker spent the first month after his operation, have planned a barbecue for him. And they also have talked of giving Walker and his mother a tour of San Francisco, cable cars and all, something neither has experienced.

Mr. Walker and Mrs. Mary D. Gohlke, 45, who received a heart-lung transplant at Stanford on March 9, and was released from the hospital on June 1, seem both headed for recovery.

Physicians are encouraged with what they've learned from Mr. Walker and Mrs. Gohlke. When the operation was attempted three times before in the late '60's and early '70's, seemingly insurmountable problems arose and the longest any patient survived after the operatation was 23 days. The project was abandoned.

The discovery of a drug, cyclosporin A, prompted doctors to try again. Cyclosporin A has indeed proved to be invaluable in helping the windpipe to heal properly and preventing life-threatening infections.

Although the news is nothing but good for Mrs. Gohlke and Mr. Walker so far, the operation is still experimental and it will be years before it could become routine.

Mr. Walker, who has bought his very first jogging suit—navy blue with white stripes—says that he's thankful--to the doctors and nurses at Stanford, to the donor's family, and to his mother and his own family and friends. He says he's received nothing but encouragement and help, and hope.

STANFORD—

Stanford University Medical School bestowed 141 degrees under clear blue skies but gloomy predictions that the world is suffering from a terminal illness.

"It's a gloomy subject to talk about on an exciting day," said Dr. Helen Caldicott as she began the June 14 convocation address. The speaker is an Australian-trained Boston pediatrician, who heads Physicians for Social Responsibility (PSR).

Caldicott, who has suspended her clinical and teaching duties to devote fulltime to PSR, said that the effort needed to save the world from nuclear disaster will require the sort of total commitment doctors must have to save a terminally ill patient from death.

Physicians as healers have a particular responsibility to work against the probability of a nuclear holocaust.

"This is our issue," she told the audience, "because a nuclear war is (a) medical (issue). It's not economic and it's not political. If any of us are left alive, we're the ones who are going to have to cope with the circumstances emanating from it."

People tend to block from their minds the possibility of nuclear disaster, she said, through the process of "psychic numbing," which shields the mind from having to deal with what most people would regard as the unthinkable. This psychological block must be overcome before people can effectively deal with the problem, Caldicott added.

Although the risk of nuclear war, whether by design or accident, is great within the next few years, Caldicott said that the "Patient's condition (the planet) is guardedly optimistic.

"...But if we all work together as physicians, educating our patients throughout the world, we will save this planet."

Following the speech, the degrees were presented and the 83 new doctors, five more than last year, joined together in the Declaration of Geneva oath.

-more-

The other degrees included 27 A.M.s in physical therapy, 22 Ph.D.s, four B.S. degrees in medical microbiology, and five M.S.s.

Seven faculty members were honored during the afternoon ceremony at Grant Courtyard following the college's 90th annual commencement.

Dr. John P. Steward, associate dean for student affairs, received the Kaiser Family Foundation Award for outstanding and innovative contributions to medicine.

In presenting the honor, the only award whose recipient is selected by faculty rather than students, Dean Lawrence G. Crowley praised Steward for his "global contributions to medical education," during not only his 17 years in the dean's office but also during nearly four decades at Stanford, starting as an undergraduate in 1944.

A student vote selected four recipients of the Kaiser Family Foundation Awards for excellence in teaching.

These included Norman Blank, professor of radiology, Keith I. Marton, assistant professor of general internal medicine; Lawrence H. Mathers, lecturer in structural biology; and Carlos A. Camargo, associate professor of clinical medicine in endocrinology.

All of the Kaiser teaching award winners have been selected for that honor by their students in previous years.

Receiving the Arthur L. Bloomfield Award for excellence in the teaching of clinical medicine was Thomas A. Raffin, assistant professor of clinical medicine and a winner last year of a Kaiser award.

Adjunct Professor Barbara Kent received the Lucille Daniels Recognition Award for outstanding contributions to physical therapy education at Stanford. She is a 20 year veteran here.

STANFORD—

In the early morning hours one night last autumn, Eugene Elliot was summoned to the hospital.

A man whose scalp down to his eyebrows had been ripped from his head was being flown to Stanford from Alaska, he was told.

Elliot, who is in his fourth year of a six year residency program in plastic and reconstructive surgery at Stanford University Medical Center, and three other residents were needed to assist Dr.Vincent Hentz in painstakingly reattaching the scalp and reconnecting its arteries and veins to the man's head.

More than 24 hours earlier, the 21-year-old Alaska crab packer had caught his shoulder-length hair in one of the packing machines, and his scalp had been wrenched from his skull. His fellow workers had the presence of mind to put the separated scalp on ice, keeping it from dying and enabling the Stanford doctors to later reattach it.

The operation, which lasted nearly 11 hours, was a success and the man is now sporting a new crop of hair, Elliot says. And even though a few weeks after the operation someone batted him in the head with a billy club, the scalp is alive and well, he says.

Although this is probably the most exciting and challenging operation he's been a part of—though, possibly not the most bizzare: he once was part of a team that reconstructed an ear that had been bitten off in a bar fight—Elliott says that creativity is always required in plastic and reconstructive surgery.

"Every problem is different," he says. "And the results usually give instant gratification—for both patient and doctor. You can see what's been accomplished."

"Nothing is more gratifying than fixing the cleft lip of a child," says David White, another fourth year resident. "And seeing the mother's face when her baby is given back to her."

There are 24 doctors in Stanford's plastic and reconstructive surgery residency program—four in each of the six years of the program. Not only is the program the largest in North America, it was also the first to integrate general with plastic surgery.

Traditionally, after medical school, aspiring plastic surgeons were trained for three to four years in general surgery, before specializing in plastic surgery for the last two or three years.

"A two year residency program after a general surgery residency is probably not adequate anymore," says White. "The field of plastic and reconstructive surgery has become too big to learn everything in just two years."

Although the common conception is that plastic surgery is the same as cosmetic surgery—the shaping of noses, the lifting of faces, the shoring up of sagging eye lids and abdomens, and the enlarging of breasts—cosmetic or aesthetic surgery is only a small part of plastic and reconstructive surgery.

Rather, plastic surgeons spend the majority of their time reshaping the damaged body and restoring its proper function. They reattach severed limbs, fingers and toes, fix cleft lips and palates, mend facial bone fractures, uncurl hands crippled by rheumatoid arthritis, reshape malformed sexual organs, and recover burn victims

"The plastic surgeon is an all-round surgeon," White says. "An integration of scientific understanding, technical skill, and creativity is required. Plastic and reconstructive surgery overlaps with so many areas—urology, opthamology, neurosurgery, chest surgery, and ear, nose and throat surgery—to name a few."

Since there is so much to learn, Stanford in the '60s instituted a residency program, which accepts doctors right out of medical school.

They still are trained in general surgery, but it is the type of general surgery judged to make them better plastic surgeons.

-more-

"We don't do as many gall bladders," White says.

From the beginning the residents are in the operating room, either at Stanford Hospital, Kaiser Hospital in Santa Clara, the Santa Clara Valley Medical Center, or the Palo Alto Veterans Administration Medical Center. At first, they tackle only the minor operations, such as cutting out a lump or repairing a hernia, just observing the more difficult ones.

"We work as a team and the residents operate to their level of competence," White says.

But as their competence and measured judgement increases, so do their responsibilities. The residents must increasingly call upon their creative talents.

"We sketch ahead of time what we expect to do, but we must always be ready to change plans quickly," White says.

"We make three-dimensional models and draw sketches. To be a plastic surgeon, you must be able to work out and visualize problems in three dimensions—both what a patient will look like after the next operation and after three additional ones," Elliot adds.

Residents also are able to take part in the INTERPLAST program, a non-profit group of volunteer doctors that gives free medical attention to people in underprivileged countries who are in need of reconstructive surgery. The program was started in the mid-'60's by Dr. Donald Laub, former head of the plastic and reconstructive surgery division, because he realized the great need for reconstructive surgery in Latin American countries.

Elliot has been to Honduras twice with the program.

In their fifth year, residents, if they choose, can go to another institution to acquire more experience in a particular area of plastic and reconstructive surgery.

White, who plans to concentrate on hand surgery, is spending next year in Baltimore's Union Memorial Hospital because of the volume and kind of cases referred there.

Elliot, who wants to become a plastic surgeon with ties to academia, will spend his fifth year at a hand clinic in Louisville, KY.

By their sixth and final year, with five years of experience behind them, the trainees earn the title of chief resident, and almost their wings. They are now central members of the operating team, doing many kinds of surgery.

Plastic surgery is geared to preserving and restoring the function of the body's parts, but ten years of training—four in medical school, and six in the residency program—can't help but be a little wearing on the plastic surgeon.

"Yes, I'm running from very early in the morning to late at night," Elliot says.

Yet, he quickly adds, "But I love operating, it's fun, it's challenging, it's gratifying."

STANFORD—

Stanford University Hospital daily room rates will increase an average of 10 percent beginning July 1.

The medical, surgical, and gynecology room rates will be $232 per day for ward accommodations, $247 for a semi-private room, and $287 for a private room. These are the services that most hospitalized patients use.

Medical, surgical, and gynecology patients utilizing services of housestaff physicians will pay $16 more per day than the above rates. The patient's attending physician determines whether such services are utilized.

The new rates, approved last week by the Board of Hospital Directors, represent a catch up with cost increases in providing patient care in both regular and special care units, according to Peter Levin, hospital executive director.

Levin noted that the hours of care per patient day are running almost seven percent higher than anticipated on routine care nursing units.

"The patient mix has shifted toward those patients who require a greater intensity of nursing care," he explained. "More care means more cost." Also, a severe nationwide shortage of registered nurses has driven up costs of recruitment and retention.

Levin indicated that increases reflect a move to align rates more closely to actual costs of providing different levels of nursing services. Rates for some specialized units such as intensive and coronary care will rise an average of 9.2 percent, obstetrics 9.7 percent, basic nursery 9.9 percent, and intensive care nursery 2.9 percent.

He said that increases in x-ray, laboratory and other ancillary services and further room rate adjustments will be forthcoming for fiscal 1981 beginning in September.

"The July increase reflects only unexpected costs in the current year," Levin noted. "Continuing inflationary pressures and reduced reimbursement from the government for care to Medicare and Medi-Cal patients will necessitate further increases for the coming year."

Patient revenues make up 99 percent of the Hospital's funds. The Hospital has neither tax support nor endowment income.

STANFORD—

Stanford University medical researchers Monday, June 15, announced they are looking for volunteers to participate in a $2.6 million randomized federal study of two drugs that seem to cure hepatitis B, a liver disease that permanently afflicts more than 100 million people throughout the world.

Under a five-year contract from the National Institute of Allergy and Infectious Diseases, Dr. Thomas C. Merigan of the Division of Infectious Diseases and his colleagues will study interferon, an antiviral substance produced by the body, and another drug, adenine arabinoside monophosphate (Ara-AMP).

Merigan's research as well as other published studies show that the two drugs used in combination or alone have produced cures in a significant number of patients with hepatitis B.

In such patients, according to Merigan, there was either transient suppression or enduring eradication of Dane particles in their blood.

Dane particles, named for the British electron microscopist who first saw them, are the complete form of the hepatitis B virus and contain surface antigens and other markers of infection.

In the United States, approximately 10 percent of patients hospitalized with acute hepatitis B become chronically infected, and they continue to carry Dane particles.

According to Merigan, such patients are major potential transmitters of hepatitis B.

Presently, there is no effective treatment against hepatitis B. For this reason, Merigan explained, discovery of a cure would be significant for the tens of thousands of Americans who are hepatitis carriers. These include doctors, dentists, and nurses who can no longer work in their professions or jobs, as well as clinical laboratory personnel.

Merigan said Stanford has used the drugs in 44 patients over the past five years to gain trial experience and to determine the optimum dosage schedules for producing enduring hepatitis eradication.

"We are now ready to extend our initial observations, for only in a controlled trial can the real usefulness of such therapy be determined."

Merigan said the volunteers will be divided into three groups. One group will receive injections of Ara-AMP alternating with interferon, the other Ara-AMP alternating with a placebo. A third group of volunteers will receive a placebo alone.

Volunteers will be placed in the groups randomly, he said, and neither they nor their doctors will know which group the volunteers are in.

-more-

"This is a standard scientific procedure which allows researchers to work out the effect of any treatment without being biased by prior expectations," Merigan said.

He stressed that even if a volunteer receives a placebo during the study, he will be no worse off than he is now.

"If the treatments prove effective," Merigan said, "patients who received the placebo will be treated at the end of the study."

The volunteers in the study will be hospitalized for a few days during early treatment at Stanford, and blood samples will be drawn. A liver biopsy will also be obtained prior to and after therapy, and one and two years later. Liver biopsy, using a hollow needle, is a commonly used technique for obtaining liver tissue to analyze under the microscope.

"The biopsy is important," Merigan said, "to determine the degree of hepatitis damage to the liver, and to evaluate the effectiveness of treatment on the virus in the liver."

The human leukocyte interferon will be supplied for the study by the antivirals substance program of the National Institute of Allergy and Infectious Diseases. NIAID obtains its interferon from the Red Cross Blood Transfusion Center in Helsinki, Finland.

The drug, Ara-AMP, will be supplied by Warner Lambert/Parke Davis and Company of Ann Arbor, Michigan, under an investigational drug permit issued by the Food and Drug Administration.

Merigan said creating public awareness of the need for volunteers with chronic hepatitis is an important first step in the research.

"We'll have to screen a lot of patients in order to get those who are interested and who have the right characteristics in terms of the nature of their hepatitis infection," he said.

Approximately 150 patients will be accepted. They will be mostly from the Bay Area, Merigan said. Patients living farther away will be considered only if they can come to Stanford for the required weekly studies.

Merigan's collaborators in the project are Drs. William S. Robinson, Peter B. Gregory, Coleman I. Smith, and Lynn W. Kitchen.

Patients willing to volunteer in the study should call (415) 497-5715.

STANFORD—

Sometimes most of the kids around Stanford University Hospital's labor and delivery unit belonged to Barbara Petree.

"There were a lot of times," recalls Petree, "when I would come into work the evening shift with my four kids and Jan Choyce's three kids. I'd leave all seven in the waiting room, and Jan (another nurse in the unit) would take them all home and take care of them until I would get off."

Petree's story of juggling child care with a career may not be unusual in a modern hospital. But her professional performance is not typical, as evidenced by the handlettered sign Choyce and some of the 54 fellow nurses and assistants put up in the ward Petree heads as clinical nursing coordinator.

The poster identified Petree as the hospital's "employee of the year" an honor spawned by the nomination of her colleagues, subordinates and the doctors she works with.

There were 30 other nominees for the Thomas A. Gonda Employee of the Year award, but on May 29, Petree walked to the podium to receive the coveted plaque.

Petree may be humble, respectful and gracious, but she isn't coy—in a recent interview she explained why she might have been chosen.

"I'm people oriented. I care about the staff and this department. I'll try my best to change my people's schedules or arrange days off or whatever might be needed.

"If people are having problems at home, for example, many times they'll tell me what the problem is, and possibly I might be able to arrange their schedule for them so that they can do something a little easier or perhaps a little less stressful. People's needs are met.

"But that's been the philosophy even before me.

"Also, I'm confidential with information that people give me.

"And courtesy is one of my biggies. It comes naturally, but it's very important to me. There's very little courtesy in a hospital in general, but I think it's very important."

Professional excellence is clearly important, as evidenced by the statement of a Medical School faculty member who nominated Petree:

"It is through her concerted effort that a quality tertiary perinatal unit has been developed at Stanford Hospital."

And recently she was elected vice chairman of the California Section of the Nurses Association of the American College of Obstetricians and Gynecologists.

-more-

During 25 years in the field, Petree has seen many changes in nursing:

"Nursing has changed tremendously. The focus has changed significantly so that it is patient directed."

In the past, she said, nurses would "go in and perform various procedures on patients.

"Then you would leave them.

"Now you spend more time with patients and the family. Of course we have a lot more ancillary personnel, which helps tremendously. Nurses don't spend as much time cleaning rooms and performing housekeeping tasks as in the past.

"The patients have demanded more personalized care. We've learned a lot more about the needs of the pregnant patient and family and some of the stresses involved."

"The patients are older and there are a lot more wanted babies these days. We're getting a lot more mothers in their mid-30s, and believe me these are very wanted babies."

The father's role has grown over the years, since both parents participate actively. "The parents are very well informed and this helps," she says.

Stanford in 1967 was a pioneer in having fathers in the delivery room.

"We still have a waiting room for fathers," Petree notes, "but it's hardly ever used. They're right in their with their wives."

Another change involves the rare but sad moments when the delivery is stillborn or deformed.

"We used to protect the mother by taking the baby out of the room, and now we don't do that—it's still her child, so we'll wrap the baby up, we'll take photographs of the baby if that's what they wish, we'll let them hold the baby if they need to go through all of the grieving process."

Petree said she was skeptical when the procedure for handling stillborns was established a few years ago.

"I could see the rationale behind it, but it seemed sort of cruel. And yet, the more you work with families who have had this problem, and the more you see how grateful they are that you let them deal with part of life, the more of a believer I become."

Technologically, mothers can be prepared for both happy and sad news through the use of equipment such as electronic fetal monitoring.

"There are very few surprises," Petree says.

During the years, the nurses, too have changed in that the latest crop "have not spent a lot of time with patients. They have been focused on a college campus and the time that they spend in the hospital is much less than we had.

"But on the other hand, they are extremely well educated, and that's what the nursing profession needs. They also do a great deal of thinking for themselves."

The older nurses, Petree says, must take responsibility for keeping up with their younger colleagues by learning modern science.

-more-

"What we have had to do is keep up on the physiology. I took a physiology course a number of years ago, and the instructor asked us who had taken an earlier course without DNA and RNA. My hand went up."

Yet despite a possible science education handicap, Petree believes that the older nurses may be sharper in picking up clinical symptons.

"For example, if a patient in our department were dehydrated, we would know they were dehydrated because they weren't putting out urine, because their tongue was beginning to crack, or some of the other signs.

"Younger nurses could give us the physiological base for what is happening to their body. But you need both.

"We also serve as role models for the younger nurses, most of whom are students. The average length of service in this ward is 12 years, so we really don't get too many new nurses, and those who come to us usually already have obstetrical experience. So our contact is with student nurses.

"We teach that you have to fit in with the patient's world. If a patient is extremely nervous, then we have to be even calmer than usual."

The experience raising four children might be helpful at work, but Petree is cautious about drawing parallels between having your own kids and functioning effectively in a labor and delivery ward.

"I don't think that you have to have children to be a good nurse in this department," she said.

"But it can be nice if you do have something to relate to, because patients feel a little more comfortable. They always ask, 'how many children do you have?'"

In the early 1970s, Petree was asked whether she wanted to become a head nurse.

"At first I thought, 'no.' But then I began to think about it.

"I decided I wanted something more. I always enjoyed leadership positions. I felt I was ready for a larger role in nursing. With the head nurse position you still have an opportunity to care for patients, which is very satisfying for me."

While Petree has kept pace with modern developments in her work field, her marriage, she says, reflected current values from the start—from a time when equal roles in marriage were not always accepted.

"It's been an unusual marriage," says Petree. "My husband believed right from the early years that we should share some of the childrearing and some of the responsibilities. He had his own business (as a paperhanging contractor) so he was able to spend more time caring for the children."

The Petree family, she says, is unusual in other ways, and perhaps this includes group communication.

"When I thought about going back to school, we sat down as a family and discussed how chores could be divided up, and what they expected of me.

-more-

"One thing they said they wanted of me was to be available Friday nights, because the two children played in the band and wanted me to come see them. I also told them what days I needed to study."

School for Petree meant management studies she found important for her role as clinical nursing coordinator.

That period of schooling was among the hardest of her life.

"I'm an evening person, so probably the early morning was the worst time for me, getting up at 5:30 and having to come in early to work, knowing that I would have to face school until 10:30 at night."

Although she thought about quitting several times, "I kept going. I guess it's a basic philosophy that I have—if you start something, you should finish it."

Finally, the effort was rewarded with a masters of arts in management from the University of Redlands, achieved with full cooperation from the family.

"At graduation time my youngest daughter said, 'Oh terrific, now you can take over the laundry again.'"

Petree, a third generation Bay Area resident, has been at Stanford Hospital and a Mountain View resident, since she and her husband, Warren, moved south from San Francisco 20 years ago.

"We had two small children, and we just didn't think the city was the best place to raise them."

Petree is satisfied the decision was wise.

"We are a little unusual, in that our kids still do things with us—camping, trips to the city, visiting relatives, whatever."

Her oldest daughter, Janis, 23, plans to follow into nursing and is currently working on a B.S. in that field at San Jose State.

Petree's oldest son, Joe, 22, is majoring in environmental management at Loyola Marymount University in Los Angeles, while her youngest son, Rick, 18, plans to attend Cal State Northridge. Sixteen-year-old Anne is in her junior year at St. Francis High School in Mountain View.

A key to bringing up the Petree kids, she says, has involved an attitude of never telling the children they *can't* do anything. Another clue may be reflected in Petree's own description of her kids now as teenagers:

"They are truly great people."

STANFORD—

Sue Addicott and about 400 of her colleagues belong to the flip-flop world of the night people.

Most days at about 7:15 a.m., the Stanford University Hospital nursing assistant drives not to work but back home to Portola Valley. Sometimes, Addicott says, she casts a smile at some of the drivers whose cars are backed up in the opposite direction. They're heading down to urban areas and the hectic world of daytime jobs. For Addicott a "day" in the emergency room is over and it's time to relax.

"It's almost a sinful wicked feeling to crawl into bed as the sun rises," says Addicott, 46.

About 10 percent of the hospital's 4,000 employees, says personnel director Don Thomas, are needed between the wee hours of midnight and 8 a.m. to perform nearly all the tasks which are performed at any other hour.(The shift is called "mornings" to distinguish it from the "night shift, which for most workers runs from about 4 p.m. to midnight.)

While many of the morning people are helping to keep patients comfortable and alive, many other workers are needed for such tasks as housekeeping, recordkeeping, or getting breakfast ready for the day.

Some of the night people accept the wee hour shift because it is the only current opening available in their specialty. But many of the Stanford Hospital workers on duty after midnight have specifically requested that shift.

A 12 to 14 percent pay differential, promotion possibilities, an opportunity to spend more daylight hours with family, or the need to spend the day in school, on another job or outside playing in the sunshine are among reasons cited for selecting the reverse regimen.

But for at least a few, the routine has become the normal way of life. Marguerite Brickner has spent most of her 36 years at the hospital working nights, mostly in the sometimes hectic but usually upbeat world of the well-baby maternity ward.

"I guess I'm just a night person," explains Brickner, the hospital's longest-serving employee.. "I'm just not alert during the day."

But Brickner has another reason for her schedule, an explanation echoed by many of her colleagues.

-more-

"There just isn't as much confusion around here," she says.

Addicott agrees:

"It's somewhat less of a Greyhound bus depot syndrome at night," says Addicott. When you're busy, you're very busy, but there is a clear idea of who is doing what . . . . Many of the people here are the same, and we do get used to working with each other."

Dick Tashiro, 29, who alternates as the lone pharmacist after midnight, says he enjoys the opportunity to work independently.

"I get to do things the way I think they should be done," he says.

Anna Gerac-Huwel, North ICU charge nurse and a 10-year Stanford Hospital veteran, thinks "you're not living with the hustle-bustle and bureaucracy of days....I think there is a feeling that we're all in this together."

For many of the night people, the work schedule just comes with the territory and is an issue perhaps unworthy of contemplation.

"If you're going to do floors, you sure can't do them in the daytime when you got a lot of people around," says Cleveland McDonald, a housekeeper who receives extra money for running a floor polisher, a task which surely can't be done when visitors, administrators, and the larger day staff are glutting the corridors.

For Frazier Tillmon, a job as night security guard at Hoover Pavilion is a second source of income. He works days as a school aide.

In the basement each weeknight at the communications hub is Beth Griffith, who has worked that shift on the switchboard for 29 years. Over the long span of years her reasons have changed from practicality to normality.

Back in the '50s, Griffith explains, working nights "was convenient. I was always home to feed my children breakfast and see them off to school. I was home just like a housewife would be.

"Now after half a lifetime, if I would have to work days, I probably would zombie my way through it."

More has changed for Griffith over the years than the expectation of several decades past that women stay home and be housewives. With her children grown and society changing, it is Griffith's husband who has breakfast waiting for her when she returns to their Menlo Park home after each shift.

Griffith is another wee hour worker who stresses the feeling of independence which comes from working all night.

"You really don't have that problem of having someone standing over your shoulder as long as you know what you're doing and are willing to do it."

The complement of morning people, says personnel director Thomas, is about 10 per cent of the total staff roster of about 4,000 persons. Most functions, including a small admissions staff and records staff are needed during the predawn hours.

While teaching and many clinical activities occur intermittently or are postponed until daytime, patient-related tasks occur at a brisk pace, says Esther Strathdee, one of several nurses who serves as clinical nursing coordinator on mornings.

"Some people have the idea that patients sleep at night. That's not really true in a hospital.

"There is a fair amount of comforting that needs to be done at night. The activity of the day is over. It's dark and some people just need to talk about the events of the day," Strathdee says.

"We actively need our most experienced nurses at night," she says, noting that backup advice and help from the most experienced doctors is often not instantly available.

It's not certain what effects the flip-flop schedule might produce on people's bodies, but all of the night people have developed patterns to manage their schedules. Some say they prefer to go to bed right after work, others choose to stay up all day and sleep right before the shift, while some take intermittent naps throughout their off hours.

An informal sampling of the night people at Stanford indicates that the vast majority sleep less than eight hours in each 24. Several longtime night people say they sleep less than four hours average each day.

Most say they are convinced they get less sleep than they did as day people. It's common for many of the night people, particularly those with outdoor interests or active social lives, to revert to night sleeping on vacations or weekends.

Many of the long time night people are anxious to tout the positive aspects of the alternative lifestyle.

"You know," says Joni Ratts, an emergency room nurse, "I just hate to get up on cold, gray mornings and go to work. This way I don't have to."

And for Anita Dunton, the morning shift admitting coordinator, the daylight means freedom to play golf.

For Judy Partridge, a refugee to California from the snows of Western Canada, working nights as a nurse leaves the day free for racquetball, jogging and poolside sunning.

STANFORD—

The Stanford University Hospital Board of Directors Wednesday June 10 selected the Seattle firm of Naramore, Bain, Brady and Johanson (NBBJ) as architect for the Hospital's $115 million modernization project.

Selection of the architectural firm is a major step in the planning to expand and renovate the Hospital's facilities that has been ongoing for three years, according to Elvia Garwood, recently named acting director of the project.

The NBBJ firm, which has specialized in health-care projects since its inception in 1943, in the past five years has designed health-care facilities with construction costs of $500 million, said Dr. Lawrence G. Crowley, vice president for medical affairs, in a report to the Hospital Board and in a letter mailed to all physicians on the Hospital's medical staff.

Among the firm's more recently completed projects, Crowley noted, are the University Hospital, University of Washington, Seattle, both the original building and additions; the Scripps Clinic and Research Foundation in La Jolla; and the St. Mary's Hospital addition in Rochester, Minnesota, including 43 operating rooms.

Crowley also outlined in his letter to Hospital medical staff further areas of progress on the modernization project, which will correct certain functional deficiencies in the Hospital as well as adding approximately 150,000 square feet of new area.

"Because no project has been built at Stanford that matches the size and cost of this one, we are conducting a national search for the person who will manage the total project," Crowley said. "In the interim, we have named Elvia Fernandez Garwood associate director and acting project director."

Garwood, who joined the University's planning office in 1976, has been associated with the Medical Center since 1979 and has had responsibility for the renovation of the Boswell Clinics in the Medical Center, a related project that is "moving ahead independently of the Hospital project," Crowley said.

Crowley also announced that Dr. Michael Eliastam, director of the Department of Emergency Services, has been appointed associate manager and physician representative on the project on a part-time basis. Eliastam will also serve as liaison with both faculty and community physicians during the program and construction phases, Crowley added.

-more-

2-2-2

Crowley has also appointed an executive policy committee to advise him on setting major goals, strategies and policy concerning the modernization project. The committee members include, in addition to Crowley and Garwood, Carl Hitchner, Medical Center counsel; David Hopkins, director of the Medical Center's office of planning and analysis; Philip Rector, director of facilities for the Medical Center; Peter Levin, executive director of Stanford University Hospital (SUH); Mary Catherine Krawec, associate director/planning (SUH); David Sakai, director of finance (SUH); James Silverman, chief of staff (SUH); and Jason Mavis, director of facilities and services for the University.

Crowley stressed that because building costs are rising rapidly, "it is prudent to modernize now." The project involves finishing shell space on two floors in one of the Hospital wings, and construction of a new wing. There will be additions to the Department of Radiology, Cardiology/Radiology, operating rooms, a new pediatric unit, a new intensive care unit, new clinical laboratories, and a 56-bed medical/surgical unit. These modifications do not represent an increase in licensed beds, Garwood notes.

In addition, portions of the present building will be remodelled to provide expanded space for other clinical programs.

Initiation of construction is expected in 1982 with completion by 1985. A staged approach to construction should minimize the impact on Hospital operations, according to Garwood.

Crowley said he also soon plans to appoint an operational advisory group to work closely with the program and design team. Membership will include Hospital administrators and service chiefs, and medical staff members.

Before construction can proceed, Stanford must file a certificate of need with the Office of Statewide Health Planning and Development, Crowley noted. This application should be filed within a year, he said, after the necessary architectural planning and cost estimates have been completed.

Mailed June 11, 1981.

EDITORS: Advance for A.M. release Thursday, June 11, 1981, to coincide with publication in the *New England Journal of Medicine.*

STANFORD—

The coming challenge to American physicians will be how to adapt to the cost-conscious 1980's, says economist Victor Fuchs of Stanford University and the National Bureau of Economic Research.

Fuchs describes three trends likely to affect medical practice adversely. They are a slower growing economy, a decrease in the rate at which the health sector increases its share of the gross national product, and the rapid growth in the number of doctors for at least another decade.

"These trends will not only have an impact on physicians in private practice, but they represent a major challenge to medical school faculties as well," he writes in the June 11 issue of *The New England Journal of Medicine.*

"Because the expansion of medical schools has been so rapid since 1950, and the slowing down will be so marked, the coming decade is likely to be particularly traumatic for academic physicians in patient care, research and teaching," he predicts.

Noting that patient care income now provides a significant portion of faculty salaries in medical schools, Fuchs says these revenues will be subject to the same competitive pressures that will face physicians in private practice.

In response to these competitive pressures, physicians will tend to hold down hospitalization of their patients, re-examine their approaches to diagnosis and treatment, and in general try to protect their own incomes.

"The solution of reducing hospital utilization in order to protect physician income will be especially controversial in universities that bear fiscal responsibility for the hospital as well as the medical school," Fuchs says.

The new, tight financial environment is also likely to result in some changes in emphasis for medical research.

"When the growth of health care expenditures seemed virtually unlimited," Fuchs says, "researchers were primarily interested in finding new drugs, new treatments, or new tests that made a positive contribution to health regardless of the benefit-cost ratio.

-more-

"All that was needed was a demonstration that the innovation was better than existing alternatives."

Under the competitive, cost-conscious conditions that are likely to prevail in the 1980's, Fuchs predicts that researchers will be expected to answer questions such as "How much better is the innovation?" and "How do the expected benefits compare with those that could be obtained if the resources were used in some alternative way?"

Ultimately, the new modes of practice and the new demands on research will have an impact on the form and content of medical education.

He believes the training of interns and residents will increasingly incorporate questions such as "Why did you order this test?" as well as "Why didn't you?"

At the undergraduate level, medical training will probably be broadened to include elements of the behavioral, social, and decision sciences as well as the traditional biological sciences.

"Adaptation will be particularly difficult," he says, "because the development of new programs, new courses, and new techniques must occur in what will be virtually a no-growth situation."

While a slowing down of the growth of medical expenditures will be achieved primarily by organizational reforms, a decrease in hours worked by physicians may be another way.

"I believe such a decrease is already occurring to a greater extent than is revealed in most surveys of physicians," he says.

Fuchs explains that doctors will be taking longer vacations, more days off, and sabbaticals.

"To the extent that the average practicing physician will be working fewer hours per year in 1990 than in 1979, he or she will be hospitalizing fewer patients, writing fewer prescriptions, and in general generating lower expenditures," Fuchs writes.

He adds that most physicians in the United States have never known a time when the real resources at their disposal were not increasing at a rapid rate.

"Thus the coming challenge will require skillful administration and considerable understanding and cooperation between the 'gown' and 'town' medical communities," Fuchs notes.

In the past 30 years, according to Fuchs, doctors have been the beneficiaries of historical developments mostly beyond their control. In the decade ahead they are likely to be the victims.

"Their responsibility, as always, is to do the best they can under the given circumstances," he concludes.

STANFORD—

The Stanford University Hospital Board of Directors Wednesday June 10 selected the Seattle firm of Naramore, Bain, Brady and Johanson (NBBJ) as architect for the Hospital's $115 million modernization project.

Selection of the architectural firm is a major step in the planning to expand and renovate the Hospital's facilities that has been ongoing for three years, according to Elvia Garwood, recently named acting director of the project.

The NBBJ firm, which has specialized in health-care projects since its inception in 1943, in the past five years has designed health-care facilities with construction costs of $500 million, said Dr. Lawrence G. Crowley, vice president for medical affairs, in a report to the Hospital Board and in a letter mailed to all physicians on the Hospital's medical staff.

Among the firm's more recently completed projects, Crowley noted, are the University Hospital, University of Washington, Seattle, both the original building and additions; the Scripps Clinic and Research Foundation in La Jolla; and the St. Mary's Hospital addition in Rochester, Minnesota, including 43 operating rooms.

Crowley also outlined in his letter to Hospital medical staff further areas of progress on the modernization project, which will correct certain functional deficiencies in the Hospital as well as adding approximately 150,000 square feet of new area.

"Because no project has been built at Stanford that matches the size and cost of this one, we are conducting a national search for the person who will manage the total project," Crowley said. "In the interim, we have named Elvia Fernandez Garwood associate director and acting project director."

Garwood, who joined the University's planning office in 1976, has been associated with the Medical Center since 1979 and has had responsibility for the renovation of the Boswell Clinics in the Medical Center, a related project that is "moving ahead independently of the Hospital project," Crowley said.

Crowley also announced that Dr. Michael Eliastam, director of the Department of Emergency Services, has been appointed associate manager and physician representative on the project on a part-time basis. Eliastam will also serve as liaison with both faculty and community physicians during the program and construction phases, Crowley added.

-more-

2-2-2

Crowley has also appointed an executive policy committee to advise him on setting major goals, strategies and policy concerning the modernization project. The committee members include, in addition to Crowley and Garwood, Carl Hitchner, Medical Center counsel; David Hopkins, director of the Medical Center's office of planning and analysis; Philip Rector, director of facilities for the Medical Center; Peter Levin, executive director of Stanford University Hospital (SUH); Mary Catherine Krawec, associate director/planning (SUH); David Sakai, director of finance (SUH); James Silverman, chief of staff (SUH); and Jason Mavis, director of facilities and services for the University.

Crowley stressed that because building costs are rising rapidly, "it is prudent to modernize now." The project involves finishing shell space on two floors in one of the Hospital wings, and construction of a new wing. There will be additions to the Department of Radiology, Cardiology/Radiology, operating rooms, a new pediatric unit, a new intensive care unit, new clinical laboratories, and a 56-bed medical/surgical unit. These modifications do not represent an increase in licensed beds, Garwood notes.

In addition, portions of the present building will be remodelled to provide expanded space for other clinical programs.

Initiation of construction is expected in 1982 with completion by 1985. A staged approach to construction should minimize the impact on Hospital operations, according to Garwood.

Crowley said he also soon plans to appoint an operational advisory group to work closely with the program and design team. Membership will include Hospital administrators and service chiefs, and medical staff members.

Before construction can proceed, Stanford must file a certificate of need with the Office of Statewide Health Planning and Development, Crowley noted. This application should be filed within a year, he said, after the necessary architectural planning and cost estimates have been completed.

STANFORD—

Dr. Roy Cohn is the new president-elect of the Stanford Medical Alumni Association, and Dr. David Rytand is the new director of alumni relations of the Stanford University School of Medicine.

Elected at the Association's annual reunion Saturday, Cohn will serve as president in 1982-83, succeeding Dr. S. Gainer Pillsbury of Long Beach.

Rytand was appointed by Dr. Lawrence G. Crowley, vice president for medical affairs and acting dean. He will succeed Dr. Gunther W. Nagel of San Francisco who served on the post since 1965. The part-time job of alumni relations director is to serve as liaison between the School and its alumni.

Cohn, who graduated from Stanford Medical School in 1933, has been a member of the Association's board of governors and member of the editorial committee of *Stanford M.D.*, the magazine of the Association. He is recognized as a respected clinician with an active surgical schedule and as a stimulating teacher of medical students and residents.

He has served on the faculty since 1938, and was the first holder of the Walter Clifford Chidester and Elsa Rooney Chidester Professorship in Surgery until he became emeritus professor in 1975.

Rytand, chief of cardiology at Santa Clara Valley Medical Center, was graduated from Stanford in 1933, and was the Arthur Bloomfield professor of medicine until he became emeritus professor in 1975. Rytand also is past president and treasurer of the Association.

STANFORD—

Mary Gohlke and Charles Walker, two ordinary people whose immediate goals range from returning to work to riding a bike to eating French food, told reporters Friday they were grateful to be alive.

Gohlke, a 45-year-old newspaper advertising executive; and Walker, a 30-year-old mortician whose illnesses have kept him out of the job market, faced news reporters here at Stanford University Medical Center, and described their zest for life and the unusual operation which has made continued living possible.

Walker said he is anxious to leave the hospital and return to work. But he is also anxious to try some simple pleasures his weak heart and lungs have denied him for the three decades of his life.

I want to "ride a bicycle for one....I've never ridden a bicycle. I just want to do the things normal people do at 30 years old.

Walker also says he wants to take his dog for a walk around the block, a seemingly simple and easy task, but one which his frail health has prevented him from accomplishing for two years.

Mrs. Gohlke is looking forward to returning to the hectic pace of work at the *Mesa Tribune*.

"I see no difficulty in returning to a normal kind of life.

"I may cut (back from) 12 hour days and go to 10," she quipped.

Among lighthearted goals, Mrs. Gohlke is hoping for a meal in a French restaurant. Released from the hospital on June 1, Mrs. Gohlke has already left her apartment for a luncheon out, but the French meal was yet to come.

With a desire to live, Mrs. Gohlke sought out the heart-lung procedure and didn't hesitate when the opportunity became reality in March.

"What choice did I have. It was taking a chance on that (operation) or dying. I had anywhere from six minutes to six months to live.

"I didn't feel like a hero or anything. As I have said before, we'd still be in the trees eating bananas if we didn't try anything.

"It was time to make a decision, and I chose to have it done."

-more-

Although expressing extreme gratitude to the families who donated the heart and lung of their loved ones, Gohlke and Walker both firmly expressed the conviction that their bodies are now a functioning unit and their own.

"I just feel it was just fantastic," said the bearded Walker. "I can't be thankful enough to the family who has been so generous to donate the organs of this gentleman who was killed, and I just feel so much better since it was done that I can't be thankful enough for it.

"And I don't really think of them as someone else's organs now. They're mine, and they're doing a beautiful job for me."

For Mrs. Gohlke, the donated heart and lung is part of the continuation of life.

"It's like I used to tell the children when we talked about death. They asked questions. I think things just continuously go on.

"It's like the flowers become dormant in the fall and are there again in the spring, and I think the same kind of thing in regard to the donor organs. I've always thought as long as you remember someone's name, they're never truly dead.

"And I will always remember this donor."

Mrs. Gohlke says that generally she feels well, "and the only thing that I don't like is the shaking.

"And they tell me that will take about six months to subside. It's bothersome when you're eating, when you spill your food all over your clean clothes.

"But it's little enough payment for living."

Mrs. Gohlke is a bit hesitant to advise other persons who might undergo the experimental procedure, "but I think they need to approach it with hope, and faith in their doctors and courage and a belief that they're going to make it.

And she points to herself and Charles Walker as examples of how much hope the procedure can offer.

Mrs. Gohlke, of Mesa, Ariz., received her new heart and lungs March 9. Walker, of Binghamton, N.Y., was given his new heart and lungs on May 1. He was transferred from intensive care to a general medical ward on June 2. Currently, he is lifting light weights and continuing with an active physical therapy program.

Both Walker and Gohlke suffered from terminal heart and lung defects and were offered little likelihood of survival without the radical surgical procedure. Mrs. Gohlke had essential pulmonary hypertension, and Walker was born with a congenital heart defect and his lungs had become damaged because of his poorly-pumping heart..

STANFORD—

Dr. Bruce A. Reitz, the cardiovascular surgeon who is the head of the heart-lung transplant team, is encouraged by the progress so far of the two heart-lung recipients.

He expects gradual improvements in Mrs. Gohlke's and Mr. Walker's ability to do things, and sees no reason why they could not fully recover to lead normal lives.

Reitz shys away from saying that the heart-lung operation can be termed a success, as reported in several newspapers. He feels it is still too soon after the operation, and two patients are hardly enough to judge if the operation will prove helpful enough to one day become routine. Much has still to be learned, he says.

But the first two operations have taught him and his colleagues good things already.

"We've learned that the operation works," Reitz said.

"Both patients' windpipes healed without complications, and the lungs are functioning without being innervated."

In the majority of previous heart-lung and lung transplant attempts, the windpipe failed to heal properly, leading to infection, air leakage or bleeding. That problem apparently has been overcome by a recently discovered drug cyclosporin A, which doesn't interfere with the weeks-long mending process.

Cyclosporin A, which has been billed as essential to the operation, has proven to be an invaluable drug, Reitz says, but not a magical one.

"It is not specific, and it must be used in combination with other drugs," he says.

Still, all in all, cyclosporin is proving to be key in the operation. Reitz says that lung transplant operations, which had been discontinued several years ago because of the dismal survival rate, will probably begin again soon in New York because of the drug.

Reitz also credits much of the recovery of Mrs. Gohlke and Mr. Walker to the experience gained during Stanford's 13-year-old heart transplant program. Doctors, nurses and therapists are attuned to the problems and complications encountered by transplant patients.

Dr. Reitz says it will be many years before the operation may become routine. Stanford is the only center doing the operation, and to his knowledge, no place else is planning to perform the operation.

"We'd like to make the heart-lung a model for how new therapies should be evaluated and the findings made available to other groups.

-more-

"We plan to continue our work in the laboratory with the monkeys, and to carefully select patients for the operation."

For now, Stanford only plans to do four of the operations a year.

"We want to learn as much as we can from each operation, so that the next patient can be benefited."

Dr. Reitz and the transplant team operate on two or three monkeys each month. Two of them, Gustav and Mom, have survived over a year and a half after the operation. The animal work layed essential groundwork for the first human operation.

Now, the researchers are continuing the experiments with the monkeys to work out optimal drug dosages and combinations, and to study the long-term problems encountered in heart-lung transplants.

No one has yet been selected to be the third heart-lung transplant recipient, but Reitz has received over 100 phone calls and letters from physicians and patients inquiring if they could qualify as a candidate.

The standards are now very stringent, and few people qualify. In the future as more knowledge and experience are gained, the standards will be relaxed and the number of operations done each year will be increased, he says.

Dr. Reitz says one of his most difficult tasks is in selecting the patients.

"It is so hard to know if someone is ill enough that he is in his last three to six months of life."

STANFORD—

Women who have been successfully treated with drugs or radiation for the cancer known as Hodgkin's disease can become pregnant and give birth to normal children, according to results of a study by cancer researchers at Stanford University School of Medicine.

Twenty percent of the entire group of women surveyed following treatment successfully became pregnant, and no birth defects were found among the 24 infants born. Among 28 pregnancies, there were 21 normal live births, (including one set of twins), two premature infants and one low-birth weight infant. All of these children are developing normally, the researchers report. Five of the women who became pregnant elected to abort the pregnancy.

The study was carried out by questionnaires and interviews involving 103 women who received treatment between the ages of 13 and 40.

"It is the first major study of this kind," said Dr. Henry S. Kaplan, D'Ambrogio professor of radiology, one of the investigators. "The results are positive." Details of the study were published in the June 4 issue of the *New England Journal of Medicine* by Kaplan and Drs. Sandra Horning, Richard Hoppe and Saul Rosenberg of Stanford.

Although 20 of 26 women in the study who stated that they had tried to have children succeeded in becoming pregnant, "any conclusions drawn from our observations must be guarded," the researchers said. "Many sexually active women did not use birth control because they assumed that they were sterile."

In addition, "larger populations of patients with similar treatment characteristics and longer surveillance times are necessary to completely assess the effect of therapy on offspring."

Hodgkins disease is a cancer of the lymphatic system which can be treated with combinations of anticancer drugs, doses of radiation directed at the lymph organs throughout the body, or by a combination of both of these techniques.

Reproductive potential, as determined by menstrual activity and incidence of pregnancy, was more strikingly impaired among the women who received radiation therapy and drug therapy together in a treatment program than among those getting radiation therapy or chemotherapy alone, the researchers reported.

It has been known for some time that both radiation and drug therapy for cancer can affect reproductive potential, the researchers noted. But insufficient information has been available "to allow professionals to counsel young women regarding the effects of current treatment programs on ovarian function."

Most of the women, 69 percent, were reported to be menstruating following their cancer treatment while 31 percent of the women in the study failed to menstruate following therapy and may be sterile.

Age at treatment and the degree of exposure of the ovaries during treatment were the most important factors in predicting pregnancy, the researchers discovered. The older women were when they underwent therapy, the less likely they were afterwards to resume menstruation.

"Advances in the treatment of all stages of Hodgkin's disease have led to the expectation of long-term survival in more than 70 percent of patients," the doctors noted.

As a result, concerns about quality of life for survivors have assumed greater importance. "The probability of maintaining reproductive function, becoming pregnant, and delivering a normal child is important to young women anticipating successful therapy for Hodgkin's disease," they added.

STANFORD—

A final report of recommendations to resolve conflicts over medical staff privileges in Stanford University Hospital was unanimously approved Wednesday, June 3, by a liaison committee of community and faculty physicians.

The report, transmitted to Stanford University Hospital Board Chairman Donald Kennedy, paves the way for development of a new Hospital Board policy concerning access of community physicians to hospital based services and laboratories.

This step, Kennedy said, will be undertaken by an ad hoc committee of the Hospital Board headed by Mrs. Linda Meier. The committee will prepare a newly drafted policy which is consistent with the contents of the report.

Members of the Meier committee are William E. Ayer, William F. Massy, Dean Morton, Frank Roberts and Kennedy, ex officio. The committee will present recommendations to the full board sometime this summer.

Dr. Lawrence G. Crowley, vice president for medical affairs and co-chairman of the Palo Alto Community Physicians-Stanford Medical School Liaison Committee, said he is very pleased that final agreement has been reached.

"It provides a fair and equitable approach to resolving the differences dividing the full-time faculty and the community physicians, and enhances the unique historical association of the Stanford University Medical Center and the City of Palo Alto," Crowley said.

He added that such differences are natural in a University teaching hospital in which full-time faculty responsible for clinical academic programs and community physicians striving to provide comprehensive care for their patients must co-exist.

Dr. Walter Arons, a community physician and committee co-chairman, said: "The agreement is a significant document that deals successfully with the questions raised by the August 1, 1978 memorandum."

"The issues were obviously difficult," he added referring to the two and a half years of negotiations. "But the fact we have an agreement is a measure of the desire of both sides to work out a solution."

The memorandum in question touched off a controversy because it excluded future access of community physicians to some specialized hospital-based services. A liaison committee was formed to grapple with the issues. Even though both sides had agreed early that community doctors should have

-more-

limited access to specialized services, the main point of contention was centered on the rules for replacing those community physicians who retired.

The key elements of the liaison committee recommendations are:

- Community physicians should continue to have controlled access to the hospital-based services in which they now hold privileges.
- As present community doctors holding staff privileges in the designated services leave or retire, they will be replaced by community doctors who hold voluntary clinical faculty appointments and actively participate in the teaching and clinical research program of the Medical School. It was recommended that a review of the staffing of these labs and services by the Board would be required at least every five years.

Associated with the report are new guidelines regarding the appointment and promotion of clinical voluntary faculty. The policy guidelines are believed to be important because privileges in the hospital-based services have been generally limited to physicians holding faculty appointments.

Voluntary clinical faculty guidelines were developed by a committee consisting of equal numbers of full-time faculty and clinical voluntary faculty, headed by Dr. John L. Wilson, Associate Dean for Faculty Affairs.

The guidelines include criteria for appointment, reappointment and promotion of the voluntary clinical faculty, and formal appeal mechanisms for review of negative decisions.

A special class, clinical associates, has been proposed for qualified voluntary clinical faculty physicians for whom there are no openings in the appropriate department or service at the time of the appointment. The number of clinical associates will be limited to 30, and they will make their patients available for teaching if needed.

Because of the complex relationships of the community physicians to Stanford, Arons termed the document as "perhaps the most detailed clinical faculty document in the country."

"It provides community physicians on the clinical faculty a greater degree of protection from arbitrary decisions, and it is a democratic document," he said.

Arons said he was optimistic that the current agreement would provide a firm basis for discussions of future issues between the two groups as they arise.

The liaison committee, in addition to Arons and Crowley, has included Malcolm Bagshaw, John A. Collins, Conrad Gullixson, Robert Jamplis, George Janetos, C. Philip Larson, Peter J. Levin, Burt McDowell, Linda Meier, Kenneth L. Melmon, Robert M. Rosenzweig, and James F. Silverman.

STANFORD—

Barbara Petree, a 20-year nursing veteran at Stanford University Hospital, was named the 1981 Thomas A. Gonda Employee of the year.

Petree, who serves as a clinical nursing coordinator assigned to labor and delivery, was presented the top employee award at a May 29 banquet ceremony by Dr. Thomas A. Gonda, the former director of Stanford Hospital and the man for whom the annual prize was set up to honor in 1975. Gonda currently serves as chairman of the Department of Psychiatry and Behaviorial Sciences in the School of Medicine.

The Gonda Award winner was selected by a committee from among 31 persons nominated by fellow employees.

"We felt not only that Barbara Petree had distinguished herself over a wide range of activities," said hospital personnel director Don Thomas, "but a wide range of people both in and out of the hospital recognized these accomplishments."

One nomination letter said, "It is through her (Petree's) concerted effort that a quality tertiary perinatal unit has been developed at Stanford Hospital."

Recently, Petree was elected vice chairman of the California Section of the Nurses Association of the American College of Obstetricians and Gynecologists.

Colleagues praised Petree, a Mountain View resident, for her excellent empathy with patients and families.

"I'm profoundly honored," said Petree during an emotional speech at the award's banquet.

In addition to the Gonda Award, five other Outstanding Employee awards were given to runners-up at the 23rd annual hospital awards banquet.

These certificate winners included Hedy Dumpel, a staff nurse; Betsy Buck, a secretary in the EEG lab; Willie Hall, a carpenter for the Facilities Division; June Ogilvie, the clinical nursing coordinator for West IIA; and Ida Huggins, a unit service assistant at the east nursery.

Also, 351 hospital employees received pins or other engraved items honoring five to 30 years service.

The lone 30-year honoree was Virginia Howe, who works in the preadmission area.

Note to Editors: An interview with Mrs. Gohlke and Mr. Walker will be available Friday, (June 5) P.M. The press conference is being held on a pool arrangement because of the inadvisability of having large numbers of persons around the patients who are on immunosuppressive drugs. Members of the press pool have already been selected; in an effort to be equitable, there is a representative from television, radio, newspaper and wire service. Detailed information as to where transcripts and videotapes of the interview can be obtained will be released on Thursday, June 4.

STANFORD—

Mary D. Gohlke left Stanford University Hospital yesterday (June 1), 85 days after she received a heart-lung transplant.

"I'm glad I went through with the operation," said Mrs. Gohlke. "I'd do it again. I've a ways to go before I get my strength back, but I'm working on that."

Mrs. Gohlke, 45, became the world's fourth heart-lung transplant recipient, the first one in ten years, on March 9. The longest any of the other recipients, who were transplanted between 1968 and 1971, lived after the operation was 23 days. But a recently-discovered drug, cyclosporin A, greatly increases the chances that transplant recipients will be able to recover fully and lead a normal life.

"I'm working to get back to my family, to my job," said Mrs. Gohlke, who before her illness was advertising executive of the *Mesa* (Arizona) *Tribune*.

She will live in the Stanford area for two to three more months so that doctors can further adjust the doses of the medications she must take the rest of her life and can keep a close watch for any signs of rejection of her new heart and lungs. After that she plans to return to her home in Mesa, Arizona.

A more immediate plan after her long hospital stay is to have lunch at a French restaurant soon

The news is also good for Charles Walker, 30, of Binghamtom, New York, who received a heart-lung transplant at Stanford on May 1. In satisfactory condition, he was transferred from the Hospital's intensive care unit today (Tuesday, June 2) to a private room on a general ward.

He's now riding an exercise bicycle a half mile a day, lifting light weights, taking walks, and treking up and down stairs in an attempt to build up his strength.

"I'm so thankful for the heart-lung program," he said. "It hasn't been easy, but I feel so hopeful. This is about the best I felt in my life. I've been off oxygen for days. I feel I've a whole new lease on life. The doctor told me I didn't just get a pair of lungs, I got a Rolls Royce of lungs."

-more-

Both patients have been cheered by the good wishes they've received from all over the country.

Walker says since his operation he's received 800 to 900 cards wishing him well. One Syracuse, N.Y., woman, who signs her name only as "Phina", has sent him a card with a dollar enclosed for luck every day since his operation.

She also arranged for a shiny new ten-speed bicycle to be waiting for him when he goes home. Walker, who was born with a congenital heart defect, had expressed the hope that the operation would allow him to learn to ride a bike, something he's never been able to do because of his chronic illness.

Mrs. Gohlke, who had essential pulmonary hypertension and spent the first 59 days after her surgery in the intensive care unit, has been during the last month in a private room in a general ward. Ten days after the surgery, she was beset by a mild rejection of the new heart and lungs, but that was completely controlled within a week, and her recovery has been steady, although slow, since then.

Four heart biopsies have disclosed no rejection problems for Mr. Walker.

Mrs. Gohlke's and Mr. Walker's operations are the culmination of more than two years of experimental work on monkeys, conducted by Dr. Bruce A. Reitz, the cardiovascular surgeon in charge of the heart-lung transplant program, and his associates in the Stanford cardiovascular laboratory.

Reitz stresses that the operation is still experimental, and only time and experience will tell whether it will be done routinely. For now, the Stanford team plans to do four of these operations a year, Reitz says. He estimates that because of the very strict selection process, very few persons would qualify as candidates. In the future if results are good, the number of operations done each year will be increased, he says.

No one is now waiting for the third transplant.

Costs for the operation, with its attendant long hospitalization, are estimated to be between $75,000 and $100,000.

STANFORD—

Sheldon King, director of the hospital and clinics at the University of California Medical Center in San Diego, has been named executive vice president of Stanford University Hospital effective November 1.

The new appointment was announced recently by Dr. Lawrence G. Crowley, vice president for medical affairs and acting dean of the School of Medicine.

In addition, King will succeed Dr. Peter Levin as executive director of Stanford University Hospital and associate vice president for medical affairs. Levin, who has resigned, is continuing as a Hospital consultant. In thanking Levin for his direction of the Hospital since 1977, Crowley cited his administrative leadership which has made the Hospital much more responsive to patients' needs.

In announcing King's appointment, Crowley pointed to his "distinguished record as an outstanding hospital administrator. He is highly respected throughout the UC system and on the national scene," Crowley said, "with a strong track record of management in university-based hospitals."

King, 49, has been director of the UCSD Medical Center hospital and clinics since 1972.

He is a New York University graduate with a masters degree in hospital administration from Yale University.

At UC San Diego School of Medicine, King has also been an associate clinical professor in the department of community medicine since 1977 and has served as acting chief of the division of health care sciences.

Before becoming hospital director at UCSD in 1972, he was executive director of the Bronx Municipal Hospital Center in New York for four years. Prior to that, he held several positions at Mount Sinai Hospital in New York, including assistant director and director of planning.

He has written numerous articles dealing with health management issues and is on the editorial board of the *Journal of Medical Education*. He is also on the board of directors of the California Hospital Association.

STANFORD—

Twenty-eight-year-old Karen Wilson Tuesday, July 28 became the third person to receive a combined heart-lung transplant at Stanford University Medical Center.

After the twelve-hour operation, she was taken to the Hospital's Intensive Care Unit. She is in critical condition, but her vital signs are stable. She is breathing with the aid of a respirator, and no attempt will be made to wean her from it until her condition is more stable.

The operation took longer than the usual four to five hours because of bleeding complications resulting from the scars and adhesions left by the two major heart surgeries she had previously undergone, and the unusual anatomy of her congenital heart defect.

The blonde, blue-eyed resident of Mill Valley, Calif., went into surgery about 7:30 a.m. to replace the heart and lungs that had been faulty since birth.

A team of three doctors, Drs. Bruce A. Reitz, Norman Shumway, and John Wallwork, performed the experimental operation.

Wilson had been awaiting the operation since July 2. Her two other major surgeries were done when she was 2½ and 23. Last January, she had a cardiac arrest, which greatly restricted what she could do, and it was estimated that she had only months to live.

"I've never had any second thoughts," she said in a recent interview. "This is my only chance. The hardest part was waiting for the decision that I would be a candidate."

Wilson was born with two things wrong with her heart: a condition called transposition of the great vessels of the heart and a hole between the two lower chambers of her heart.

Briefly, normally the main vessel leading to the lungs—the pulmonary artery—is attached to the lower right chamber of the heart, and the main vessel leading to the remainder of the body—the aorta—is attached to the lower left chamber of the heart. In Wilson's heart, the two arteries had switched places, were transposed: the pulmonary artery came from the left side, and the aorta was attached to the right.

Her lungs were irreversibly damaged because of the abnormal blood flow pattern resulting from her backwards-connected heart.

Growing up in Miami, Wilson was able to attend school but never to participate in any sports or gym. She moved with her mother to Marin county in 1972.

Her mother, Betty Brashear; stepfather, Turner Brashear; and sister, Mrs. Donna Cameron, were at the Hospital during the operation.

"I want the operation because I want to lead a normal life," she said. She looks forward to learning to play tennis and pursuing her interest in photography.

-more-

The 5-foot-3, 110 pound woman said recently "I've lots of determination. I've wanted this for a long time."

Wilson says that 30-year-old Charles Walker, who received the second heart-lung transplant at Stanford on May 1, has been of immense help in reassuring her. She and Walker have become good friends, she said. He waited with her in the hours before the operation.

She read everything she could get her hands on about the first two Stanford transplants, and when she and her family was told that she was a candidate everyone cried except her.

"It's what I wanted," she said.

Stanford performed its first heart-lung transplant on March 9 on Mary Gohlke, 45, a Mesa, Ariz., advertising executive.

Both Gohlke and Walker are still recovering from their operations. Gohlke has had to be briefly rehospitalized three times for minor complications since her initial June 1 release. Walker has been free of complications.

Both are still living in the Stanford area for the time being, but may be able to return to their homes sometime in the autumn if no complications develop.

This is only the sixth time the operation has been done in the world. It was attempted three times between 1968 and 1971, but because of the complications, none of the recipients lived longer than 23 days. Mrs. Gohlke's operation was 141 days ago.

In those early attempts, the windpipe failed to heal properly, leading to infection, air leakage, or bleeding. That problem apparently has been overcome by a recently discovered drug, called cyclosporin A. which doesn't interfere with the weeks-long mending process.

Dr. Reitz says it will be many years before the still-experimental operation may become routine. Stanford is the only center doing the operation; it plans to do about four a year. To his knowledge, no place else is planning to perform the operation.

"We want to learn as much as we can from each operation, so that the next patient can be benefited to the fullest extent," he said.

He estimates that because of the very strict selection process, very few persons would qualify as candidates, but adds that in the future if the results are good, the number of operations done each year will be increased and a greater number of people may qualify.

STANFORD—

A cancer researcher and a cardiologist at Stanford University School of Medicine have been named the first two Brotman Foundation Scholars for medical research from a $25,000 gift to Stanford from the Brotman Foundation of California, located in Los Angeles.

The two scholarship recipients, Dr. Stuart Young and Dr. Jay Mason, both assistant professors, will carry out basic medical and clinical research programs as Brotman scholars.

Young is developing techniques for destroying cancerous tissue while leaving normal tissue unharmed. He is also developing improved methods for diagnosing tumors and monitoring their growth or shrinkage during therapy. He has had promising results working with contrast agents, substances that are tumor-specific and can outline a tumor for enhanced diagnostic imaging and more sharply targeted therapy. Young also hopes to develop a system for delivering tumor-killing drugs directly to cancerous tissue.

Mason is studying new ways of diagnosing and treating abnormal and potentially fatal heart rhythms. These methods include mapping the heart tissue in order to find and surgically remove the spot where the rhythm disturbance originates; inducing arrhythmia in patients in order to evaluate in a controlled setting the effects of various anti-arrhythmic drugs; and using programmable pacemakers that can be installed in a patient to sense abnormal rapid beating of the heart and, through electrical stimuli, rapidly halt the arrhythmia.

In naming Mason and Young as Brotman scholars, Dr. Lawrence G. Crowley, vice-president for medical affairs and acting dean of the School of Medicine, acknowledged the Brotman Foundation gift.

"In young faculty members such as Dr. Young and Dr. Mason, the Brotman Foundation is investing in future national leaders in medical research and education," he said. "Their research programs will certainly advance through the Foundation's generosity."

The Brotman Foundation was established in 1960 by Dr. David M. Brotman in memory of his mother and father. According to the Foundation, Dr. Brotman, who died in 1973, was one of the guiding forces in the advancement of proprietary hospitals in southern California. During his career, he was medical director and president of several hospitals in southern California and subsequently founded, and was president of a nationally known chain of hospitals.

An important goal of the Foundation is to serve the community by awarding grants to physicians who are engaged in medical research projects.

STANFORD—

New forms of a familiar substance, vitamin A , can bring relief to those plaqued by psoriasis and acne, and hold promise as anti-cancer agents. Man-modified molecules of vitamin A are proving capable of controlling severe cases of psoriasis, an incurable disease that afflicts six to seven million Americans alone.

The retinoids (a catch-all name for vitamin A and its naturally-occurring and synthetic modified forms) are also clearing severe cases of acne, and studies in animals suggest they may eventually be a weapon against certain types of cancer.

This heartening news coming in from numerous studies throughout the world had the nearly 500 doctors and scientists gathered at Stanford last week for the Third International Psoriasis Symposium in a buoyant mood.

"This is one of the most exciting drugs in the history of dermatology," opined Dr. Eugene Farber, chairman of the department of dermatology of the Stanford University School of Medicine, and president of the International Psoriasis Research Foundation, a multidisciplinary, non-profit reseach center in Palo Alto. "It is a major breakthrough."

"The retinoids are like comets in a night sky," said Dr. Constantin Orfanos, chairman of the department of dermatology in the Free University of Berlin in West Germany.

In the early and mid-70's Orfanos did the first clinical studies with the particular retinoid that is proving to be most beneficial in the treatment of psoriasis, the so-called aromatic retinoid.

"This is the first time an oral medication has had such an influence in psoriasis," he said. "Until now the only drugs that have really proved useful by themselves were the cytotoxic (cell-killing) drugs used in cancer treatment. But these drugs kill all cells indiscriminately. The retinoids are more targeted for the skin."

An especially appealing aspect of the retinoid therapy is that the messy, staining, often irritating lotions and creams of the standard assault on psoriasis can be replaced in some instances by a pill in the morning and evening.

In the clinical studies already done, nearly 90 percent of those patients whose bodies were covered with psoriasis—the most troublesome kind—were helped by the treatment, according to Orfanos. In general, 61 percent of psoriasis patients have a good to excellent response to the aromatic retinoid treatment, he said. It is particularly effective in the pustular and erythrodermic types of psoriasis, he reported.

more

The scales usually start regressing about three weeks after therapy is begun, and within an additional six to eight weeks disappear.

Also, standard therapies seem to interact with the retinoids in such a way that healing occurs more rapidly and requires smaller doses of medication.

The aromatic retinoid will probably be in clinical use in Switzerland, England, France and Germany as early as this autumn. Estimates are that it may be two to three years before it reaches the market in the United States, however. The delay is due to the stringent rules of the Food and Drug Administration, groused some of those dazzled by the drug's benefits and eager to start its clinical use.

Stanford is part of a five-center clinical study now being conducted in the United States to meet the FDA's requirements.

Even the most ardent boosters of the new drugs, however, admit the retinoids carry a baggage of undesirable side effects, and until a more risk-free type is fashioned, they will only be used to treat the most severe cases of psoriasis or acne.

The most serious undesirable effects that could potentially develop are birth defects, and woman are advised to wait a year after they stop taking the drug before becoming pregnant, says Dr. Werner Bollag, head of the cancer research laboraties of Hoffmann-La Roche and Co. in Basle, Switzerland.

The aromatic retinoid also increases the level of serum lipids, putting patients with diseases such as diabetes at a greater risk than those without the disease. Other side effects include chapped lips, a drying out of the nose and mouth lining, and peeling of the palms and soles.

The hallmark of psoriasis, which results in thick, red silvery-scaled patches on the skin, is a six to seven times faster growth rate of the skin cells than is normal. Vitamin A has long been known to control the growth and differentiation of certain types of cells, such as those found on the skin, and so is a natural for treatment. But in the doses required for therapy it proved to be toxic—arthritis-like symptoms can develop, hair fall out, skin crack and peel, and the liver and spleen enlarge.

Bollag set out in the early 1970s tinkering with the vitamin A molecule, modifying it chemically, trying to eliminate the bad and enhance the good effects.

He synthesized more than 1500 different forms, and began the Herculean task of testing them in rats. One compound, a 13-cis retinoic acid, was found to be excellent for clearing up severe, inflamatory acne; the aromatic retinoic proved to better treatment for psoriasis. A workable compound for the treatment of cancer hasn't been identified yet.

In experiments with animals, retinoids effectively combatted lung, bladder, breast and colon cancers, but their inherent toxic effects caused by their buildup in the body overshadowed their cancer-combatting qualities.

So the search still goes on for a molecule that has been tailored to counter cancer but has been rid of the properties that lead to the undesirable effects, but scientists are hopeful.

STANFORD—

Harold L. Mindell, associate administrator for engineering at Yale-New Haven Hospital, has been named director of the Stanford University Hospital Modernization Project.

The appointment becomes effective October 1, 1981, said Dr. Lawrence G. Crowley, vice president for medical affairs and president of Stanford University Hospital.

In addition, Crowley announced that Elvia Garwood will become deputy director of the Modernization Project. Garwood has served as acting director since February 1981 and will continue in that role until Mindell arrives.

Mindell and Garwood will lead the Hospital's Modernization Project team, along with Dr. Michael Eliastam, who will provide liaison with faculty and community physicians, and Malinda Mitchell, R.N., who will represent the Department of Nursing Services, Crowley said.

Mindell, 55, will be responsible for overall management, design, and construction of the $115 million Hospital expansion and renovation plan, financially the largest single construction project ever undertaken by the University or the Hospital.

In appointing Mindell, an engineer, to the post, Crowley noted his extensive experience in managing other large construction projects in health care settings, most recently a $70 million replacement facility and major renovation project at Yale-New Haven Hospital in New Haven, Connecticut.

Mindell also was responsible for operations and maintenance at Yale-New Haven Hospital, supervised design and construction of the Hospital's other renovation projects and directed an energy management program.

Prior to his position at Yale-New Haven, Mindell was division manager for maintenance at the 750 bed Hadassah Hospital in Jerusalem, Israel from 1974 to 1978.

From 1951 to 1974 he was a partner in the consulting engineering firm of Dubin-Mindell-Bloome Associates, P.C. (located in New York and Hartford) where he was responsible for design of mechanical and electrical systems on construction projects totaling nearly $1 billion.

Mindell earned a B.S. degree in mechanical engineering from the University of Michigan in Ann Arbor in 1950.

-more-

2-2-2

Garwood, before becoming acting director of the Modernization Project in February, was manager of major projects in the Medical Center Facilities Department and directed the renovation project for the Medical Center's Boswell clinics. From 1976 to 1979 she was a project manager in the University Facilities Office.

Garwood graduated from Cooper Union for the Advancement of Science and Art in New York City and she holds a master's degree in architecture from Yale University.

Initiation of construction on the modernization and expansion project is expected to take place sometime in 1982 with completion by 1987. The architectural firm handling the project is Naramore, Bain, Brady and Johanson of Seattle, which will establish a Palo Alto office for this project.

The project involves finishing shell space on two floors of the Hospital, new construction, and renovation of the Hospital areas vacated during departmental moves. Without increasing the number of licensed beds in the Hospital, there will be additions to the Departments of Radiology, Cardiology/Radiology, new and renovated operating rooms, a new pediatric unit, a new intensive care unit, new clinical laboratories and a 56 bed medical/surgical unit.

Some support areas will also be incorporated into the Modernization Project. These include consolidation of a materials management center, revising the main kitchen/cafeteria areas, expansion of the pharmacy, and extension of the loading dock and related support services.

Mailed Wednesday, July 29, 1981.

STANFORD—

The bookstore at Stanford University Medical School is scheduled to move to an expanded downtown Palo Alto location Aug. 3.

The move from a 475-square-foot store next to the student lounge at the school to the new location at 135 University Ave. at High Street will expand the floor space about five times and permit an increase of about 25 percent above the current inventory of about 3,500 titles, said Roy Hoyer, manager.

"A lot of medical schools complain about the size of their bookstore, but our situation was ridiculous," said Hoyer about the tiny bookstore which has been at the same location for about 20 years.

The move will leave the Medical Center without an on-premise bookstore, but Hoyer said he hopes increased stock, more space and longer business hours "will offset the inconvenience of the move."

The store will be open 9 a.m. to 6 p.m. Monday through Saturday, In addition, the facility will be open until 9 p.m. on Thursday.

Textbooks will be sold, and rebates previously offered to the Stanford community will be continued, Hoyer said.

Efforts were made to expand the present facility, but "despite much sympathy, neither the university nor the Medical Center has offered any hope for future accomodation of a larger store in the Medical Center," bookstore management said in a flier explaining the move.

David Mendelow, associate dean for administration at the space-scarce Medical School, said "no space contiguous to the bookstore was immediately available which could be developed economically."

The medical bookstore is a branch of Stanford Bookstore, a nonprofit corporation operated as a service to the university with a board of directors composed of faculty members and other persons in the Stanford community.

The new store will be called the Stanford Medical/Technical Division Bookstore, and will include a variety of books on a variety of scientific topics and an expanded display of medical instruments.

The store plans to mail books to customers or have books not in stock mailed directly to customers by publishers.

The tentative phone number is 327-3680. Campus interdepartment mail will reach the new facility via the main campus bookstore.

STANFORD—

A British nursing manager believes that competitive U.S. hospitals might successfully adopt some of the cooperative techniques of socialized medicine.

Comments on differences between U.S. and British health care came from Gill Greaves, the northwest Surrey divisional nursing officer, who recently completed a three-month study trip to Stanford University Hospital and other California health care facilities.

Greaves, who is in charge of both in- and out-patient nursing care for an eight-hospital division south of London, conceded she was sometimes a bit surprised by the differences between the competitive U.S. hospital system, and Britain, where since 1948, the government has paid for the bulk of medical care from taxes.

"The biggest difference between the two countries is that each hospital in America tends to function individually, whereas in socialized medicine, there's more of a cooperative approach."

Perhaps most striking, she said, was the commercial orientation encountered here.

"The competitive element is a good thing to have," she said. "But to me it's interesting to see to the extent to which that is carried, both within the institution and in competition with other hospitals. For instance the advertisements on the radio, actually marketing health—or ill health as it were.

"Whereas in Britain, the competition within the National Health Service (NHS) tends to be individual and internal and probably takes the form of competition to make waiting times less in one district than in another, or in the nursing service to reduce the turnover rate. Things of that nature."

But Greaves said the United States need not socialize its medical coverage to benefit from some of the administrative lessons she believes can be learned from the NHS.

For example, hospitals and health care districts in her country are managed by consensus, rather than as here with an administrator and assistants.

In each British hospital, the administration consists of a nurse manager, a finance officer, an administrator (in charge of the physical facilities), and three doctors who are voted into office by their medical colleagues for four year terms. The doctors include a consultant (specialist), a general practitioner and finally a community physician concerned with environmental medicine and school health.

On the divisional level where Greaves works, a similar team oversees a group of hospitals and outpatient health care in an area.

The managers meet formally to plan and review operations, and each member of the team has veto power in the decision making.

Greaves said that occasional disputes usually are resolved on the local level, since administrators are motivated to prove to their superiors that they can solve their own problems.

The consensus approach, Greaves believes, enables all management personnel to understand a wider range of problems and would be adaptable to the U.S. system of free enterprise health care.

"What I think it would mean is that there would be more discussion between departments and maybe more cooperation between administrators of different functions which could collectively benefit the hospital."

-more-

At Stanford, Duane Walker, director of nursing, discussed consensus management with Greaves during her visit and has concluded from that and other research that "nursing needs to move more in that direction.

"Nursing would have a voice in planning and delivery, programs and finances, and the joint approach already is being studied in this country," Walker said.

Greaves believes that by including nursing in the top management team, her field is better represented in overall health planning. For example, one of the eight local hospitals in her district currently is scheduled to be remodeled, "and under our team approach the nurse manager is very much involved in actually planning and designing the new hospital."

Overall planning of comprehensive care is emphasized more in Britain, Greaves believes, than in the United States, where more emphasis is placed on development of acute care.

"The way we work is to take a given community of 200,000 to 300,000 population to look at the age-sex ratio and the morbidity of that population and from there determine the pattern of service which needs to be provided for that population.

"For example, if you're living on the south coast of England, you have a high population of elderly, which means that a lot of your resources must go toward the services for the elderly. And it probably means that some of the other services need not be developed to quite such an extent as in other areas where there may be more younger people.

"So on top of that there is close integration between community services and hospital services, including extensive home visitation services for patient and relative support, as well as outpatient clinics which are part of NHS.

Greaves sees that a trend in this country toward health maintenance organizations—prepaid plans such as Kaiser—is a recognition that health care must extend beyond the hospital.

Greaves is quick to deflect a stereotype that British government functions on a maximum of clerical procedure.

"I'm amazed at the amount of paperwork which is generated here and the kind of bureaucratic work here—much of it, of course related to patient billing—which we really don't have. .

"We don't have anything like JCAH (Joint Commission on Accredidations of Hospitals) or PSROs (Professional Standard Review Organizations) which in themselves generate an enormous amount of work" because they require visiting time by medical personnel and followup reports.

"That leaves people (in British health administration) to some extent freer to be innovative and creative, albeit within a given budget," Greaves said.

But she emphasized that some paperwork is at least a necessary evil, and "I do support the idea of patient care monitoring through quality assurance programs, and I think the NHS should develop more effective monitoring."

Despite some criticism, Greaves strongly praised the physical facilities she found here and said they generally appeared to be superior to those in Britain.

Also, Greaves said that at Stanford particularly—she also visited hospitals in Yuba City and Santa Barbara and around the Bay Area—"nursing research is extremely exciting....People are making a sophisticated effort to research what techniques and care is most effective for patient treatment. The proposed liaison between nurse researchers and clinical nursing coordinators as a team approach to research is impressive, she added.

Another feature of Stanford, is a mix of teaching and community physicians, which she felt enhanced both patient care and doctor training.

3-3-3 In addition, she noted that some high technology care, such as heart transplants and kidney dialysis, appeared to be more highly developed in this country, although she questioned whether this might be the best allocation of resources, which vary between the two nations.

"The U.S. spends 9 percent of its gross national product on health, while Britain spends 6.5 percent of its gross national product. So that in itself is a difference.

"But within that it depends on your philosophy of approach whether you're going to divide that up between all ages of the population on as equal a basis as possible, or whether you're going to in fact put more of your money into acute services and less into the long stay, in which case you have a less equal approach to care. I perceive that the emphasis is much more on acute care here and on more equal care in Britain."

Another difference, which Stanford's Walker noted, is that the British hospitals are smaller and tend to be more specialized. Consequently, it could be more difficult to treat multiple problems in a single facility.

For example, Greaves' division, consists of a district general hospital with 400 beds, a 50-bed acute hospital for surgery and minor casualties, three smaller community hospitals specializing in longer term care, an orthopedic hospital and two geriatric facilities.

On the larger district level, there is a maternity hospital, a 900-bed mental handicap hospital and several other specialized facilities.

Greaves contended that while the psychiatric hospital, for example, might not be set up to handle acute medical treatment, a mental patient suffering serious physical illness would be moved to the district hospital.

"You have to decide which is the more serious problem at the moment and direct your attention to that," she said.

Britain, Greaves noted, shares a common bond with the United States in a shortage of nurses. While little difficulty is encountered in recruiting nurses to the profession, many leave after a short period to come to the United States, for example, or shift to other less straining and perhaps more lucrative fields, she said.

"We need to determine how many we need to train in order to have enough nurses available to us."

Training of nurses, she added, is different between the two nations, offering a slightly different type of training in each country.

English nurses, Greaves believes, "have more clinical experience and exposure during their training than the American nurses do. But I think possibly U.S. nurses have a better theoretical base than ours....What I have seen here is that when the nurses come out of training, they need quite a lot of support and more training in order for them to be competent practitioners.

"Whereas, I think our nurses would have had about 50 percent of their time spent in clinical areas of training as part of the work force."

In Britain registered nurses attend school, usually operated on a district basis for three years, although some degree courses combined with other nursing certificates exist.

Most R.N. courses in the United States range from two to four years.

At Stanford, Walker contended that the greater clinical emphasis in England offers no advantage.

"Our nurses have the theoretical base, and it's been proven that they will learn much faster once they're at work," Walker added.

STANFORD—

The day of nurses catering to the demands of the doctor has ended in the United States, but elsewhere, nursing never had such a surbordinate role, contends an international nursing advisor.

"In many countries throughout the world, there are very few doctors, and nurses are the only professionals that cover the health needs of people on a national level," comments Dr. Hend Abdel-al, nurse advisor for the International Council of Nurses (ICN).

For Abdel-al, whose job is located in 58 countries around the world, the most important step lies in making governments realize that both doctors and nurses have different responsibilities and make separate contributions.

During a recent visit to Stanford University Hospital, Abdel-al summarized her views by saying nursing is a profession and not a discipline. And she feels that in many nations nurses need to be more involved at the government level of health care planning.

"Nurses make up a very large part of the health services personnel," she says, "And I think we as nurses should direct our energies at really seeing the application of our responsiblities within the health services delivery system at the national as well as local level."

Abdel-al says that within those countries where nurses are found at the government level of planning for health care and the distribution of nurses around the country, officials have found it very helpful and health services have improved.

"I think it's only logical that if you're responsible for the health service delivery that you have to be responsible for planning it and implementing it as well."

As a nurse advisor for the ICN, Abdel-al spends much of her time traveling to various countries visiting or establishing nurses' associations or representing the ICN at international meetings.

The ICN is an international federation of national nurses' associations, representing 89 countries, based in Geneva, Switzerland.

-more-

Abdel-al's most recent visit was to the United States for the 17th Quadrennial Congress of the ICN held in Los Angeles in early July. Since then Abdel-al has traveled to the University of California at San Francisco and then Stanford University Hospital, observing various nursing research units.

Abdel-al's visit to Stanford on July 9 was spontaneous as it wasn't until the congress in Los Angeles that she became aware Stanford had a nursing research center, a relative rarity at hospitals.

Although Abdel-al's services and responsibilities for the ICN often vary, she currently is gathering information about the structures and locations of nursing research units all over the world.

Her main objective is to find out how research can help the development of nursing as a profession. This information will then be disseminated to the different national nurses associations within the ICN.

"I'm very glad that I came to Stanford because I find it fascinating and very important in supporting nurse's conceptions about what role research plays in our practice," she said.

"I think what I found most facinating is that staff nurses are the ones that somehow decide what are the problems and then get the help and the time for researching these problems."

Stanford's Director of Nursing Service Duane Walker felt that the visit was mutually beneficial as Abdel-al said she plans to use infomation gathered here in a paper she will present at the World Federation for Mental Health Congress in Manila next month.

"I think Stanford gained some real ground in being able to share with her what we're doing," said Walker. "The most revealing thing for me was realizing that our problems like the shortage of nurses and the image of nursing, whether it's a profession or discipline, are international problems and not just something we are struggling with in the United States."

As a Ph.D. graduate of the University of Edinburgh in Scotland, the Egyptian-born Abdel-al started her job at the ICN two years ago. Since then she has visited more than 23 countries through the French-speaking worlds of Europe and Africa and all of the Middle East.

Before coming to the ICN she was head of the psychiatric nursing department at Cairo University and was consultant to the Ministry of Health in Egypt.

From Stanford Abdel-al went to Seattle and then Manila for her meeting starting Aug 1.

PALO ALTO CITY COUNCIL CONSIDERS HMP RESOLUTION

STANFORD—

The Palo Alto City Council Monday night (July 27) postponed until Aug. 9 a decision on whether to pass a resolution formally supporting the Stanford University Hospital Modernization Plan (HMP).

The resolution is not required for work to continue on the project, but hospital officials are seeking the action as a testimony of support from the council as the HMP faces review by state and county agencies.

"We are seeking the voice of a friend and neighbor who will vouch for us as we move through the governmental approval process in the weeks, months and years ahead," Lawrence G. Crowley, nford's vice president for Medical Affairs told the council Monday.

Crowley said SUH plans to seek similar resolutions from neighboring communities in the future.

Councilmember Emily Renzel, who was absent, had written her colleagues requesting a postponement until the council was able to seek assurances from Stanford on several issues, including the issue of access to hospital-based services by community physicians and financial issues relating to the hospital and HMP.

Councilmember Larry Klein, who in Renzel's absence sought the continuance Monday night, said "it was not appropriate" for the council to become involved in disucssions of Stanford finances. But he recommended—and the council subsequently adopted unanimously—his motion that a public hearing be held Aug. 3 to discuss the access question and other issues relating to the hospital's HMP request.

The hearing would be conducted by his council hospital subcommittee which will report back for full council action on the resolution Aug. 9.

Stanford asked the council to approve a resolution saying "the City of Palo Alto supports ernization of the Stanford University Hospital."

-more-

The measure states that approval "does not constitute advance approval by the City of Palo Alto of any of the financial, environmental or physical aspects of the modernization project."

Full public hearings by the city would be held when the hospital seeks a favorable environmental impact report and building permits.

The $123.9 million HMP is intended to bring the hospital up to modern standards and fulfill the patient care and teaching needs of the community and medical center through the 1990s.

"Everything in the plan is necessary for the hospital's survival," Sheldon King, director of SUH told the council Monday.

Paul Cooney, a Palo Alto physician and clinical professor of medicine, told the council that the access question was like the "rock of Sisyphus," an obstacle which in recent years has caused discord between the hospital and some physicians and needs to be resolved.

But Cooney said he favored the HMP: "It's a given. There's no right-minded physician who wouldn't be" in favor.

Geraldine Steinberg, a lay member of the hospital board and former member of the Santa Clara County board of supervisors said "access and the need to modernize are two different issues."

Both she and Walter Arons, a Palo Alto physician who also serves on the hospital board, said that discussions between hospital and community physicians are making progress and should be conducted independently of the HMP question.

The question of access has not involved the admission of patients, since all qualified community physicians may admit their patients to SUH, and Palo Alto residents have priority for elective admissions.

At issue is the question of whether doctors who are not fulltime faculty members may have unrestricted or greater privileges to perform certain procedures in hospital or university operated labs or facilities, such as radiology.

STANFORD—

Volunteers with high blood pressure are being sought by a Stanford University professor for an experiment to test the effects of what he described as "a rapidly acting drug."

Dr. Michael Horne of the department of psychiatry said subjects should be more than 18 years old without serious complications from their blood pressure conditions.

Testing is to last about two hours and volunteers will be taking the drug, which has no known side effects, orally, Horne said. Subjects may be taking other medication which will not be withdrawn during the test.

Horne said no compensation will be provided but volunteers will be given advice on various psychological techniques to control blood pressure if they desire.

For further information, call the Laboratory of Behavioral Medicine at Stanford University Medical Center, (415) 497-6911.

STANFORD—

Dr. Avram Goldstein, professor of pharmacology at Stanford, has been selected as the recipient of the 1981 Torald Sollman Award.

The award is presented every three years by the American Society for Pharmacology and Experimental Therapeutics (ASPET) to the person who has made the most "unique and original" contributions to the advancement of research and education in the field of pharmacology.

Goldstein, a world authority on the use of methadone in drug addiction, is also widely recognized for his discovery and isolation of dynorphin, a natural brain chemical 200 times more powerful than morphine.

Goldstein will receive his award and give the traditional Sollman Oration in August at ASPET's Fall meeting at the University of Calgary in Alberta, Canada.

Sponsored by Wyeth Laboratories of Philadelphia, the award is named in honor of Dr. Torald Sollman for his pioneer work in the fields of pharmacological investigation and education.

Dr. Kendric C. Smith, professor of radiology has been elected vice-president of the American Institute of Biological Sciences (AIBS).

Effective Nov. 1, Smith will serve as vice president until 1982 when he will become president.

Established in 1947, the AIBS represents more than 8,000 individual members in more than 40 professional biological societies. The AIBS monitors federal activities important to the field of biology and provides advisory services to federal agencies. The Institute also is active in curriculum revision in high schools and colleges and publishes *BioScience* journal.

At Stanford since 1956, Smith is a leading expert in the field of photobiology which deals with the chemical and biological effects of light. For his expertise he was elected president of the American Society of Photobiology in 1972.

Smith also is a specialist on the effects of radiation on cells. In 1971 he was part of a team that discovered the mechanism by which cancer cells repair themselves after X-rays produce breaks in the DNA chain of cells.

Dr Gerald Reaven, professor of Medicine and head of Stanford's Division of Gerontology, has been selected to serve on two separate national advisory boards.

Reaven was one of 18 persons chosen by Health and Human Services Secretary Richard Schweiker to the newly formed National Diabetes Advisory Board of the National Institute of Health. The board includes 12 members chosen from the science profession or science related fields.

The Panel was formed by an act of Congress with the purpose of assisting national programs of research, health care, and education and control of diabetes mellitus.

"I think the board is a reflection of a growing perception by Congress and the Reagan Administration of the great importance of diabetes as a health care problem," said Reaven. "It's an exciting opportunity for the field."

Reaven was also recently reappointed to the Advisory Panel on Endocrinology for the United States Pharmacopoeial Convention (USP).

Serving until 1985, the panel members comprise one of 26 advisory boards which works in conjunction with USP and its drug-use information development programs.

Reaven, who first served on the board in 1976, was selected with nine other doctors by the advisory panel's chairman.

STANFORD—

From a time when fainting was the only relief from the tortuous pain of a surgical saw tearing through bone and nerves comes a collection of implements detailing medical progress in recent centuries.

Several thousand pieces of medical memorabilia, recently unwrapped after two decades of obscurity in a basement, were catalogued recently at Stanford University Medical Center's Lane Library by a surgical resident with a yen for history and collectibles.

Many of the objects pay unwitting tribute to superstition.

The oldest instrument, dating back to about 1690, is a scarifier which was used to suck blood and serum from the ill. The rationale for the painful treatment now known to be useless was the ancient belief, spawned by the Greek philosopher Hippocrates, that the body was comprised of humors—bile, blood and phlegm—which needed to be drained when one became dominant.

The scarifier consists of one or more blades, about a quarter inch long, and a separate cup. After cuts were made, the cup was placed on the body heated, so that as it cooled it would draw out blood.

Later models were equipped with adjustable blades—a testament to technological skill but still fell short of today's medical knowledge.

Dating back more than 100 years are ornately carved scalpels and saws, usually with ebony or ivory handles. The intricate, artistic designs caused death for those persons whose skin was opened, since the nooks and crannies on the sculptured surfaces were marvelous spawning grounds for infection in a day before sterilization.

As recently as the turn of the current century, specially designed forceps were used to crush the heads of infants who were too large at their moment of birth to pass through their mother's pelvis. Such devices predated the now-routine Caesarean section, which allows the baby to be removed while sparing the mother and baby's life.

From dusty boxes stored in the basement for more than two decades, third year general surgery resident Alan R. Koslow identified, photographed and catalogued the collection he estimates to be valued at about $500,000.

The pieces had been wrapped in "1959 newspapers, which gives us a clue that they were wrapped up when the Medical Center moved down from San Francisco 22 year ago," Koslow said in a recent interview.

more

Some of the more historicaly significant pieces, including an 1890 syringe kit belonging to Dr. Oliver Wendell Holmes, are on public view in a lone display case in the library. But most of the material remains locked up in a basement case awaiting available funds for permanent display facilities.

Peter Stangl, Lane Library director, said no arrangements have been finalized for public display of the collection, which he calls "significantly large.

"We are genuinely hoping to find some way to display these materials in a manner which will give them the respect they deserve. But even until then, the cataloguing efforts of Koslow enable our staff to preserve the valuable material we have or hope to receive in a safe and proper manner."

According to Koslow, "The important thing about the collection is the scope. It has an example of just about every major field, except for anesthesia."

Koslow is hesitant to rank the medical collection against other universities, but he estimates that it might be in the top 10 or so in the nation in terms of quality and quantity.

Most of the pieces arrived at Stanford haphazardly, often as bequests from widows or their attorneys, unsure what to do with a doctor's personal instruments.

But their fate until Koslow's arrival was uniform—obscurity.

"It was serendipity, really," said Stangl about how Koslow's talents were matched with the collection.

Claire Still, who retired recently as medical history librarian at Lane, chatted one day with Koslow and learned he had attended the University of Buffalo. She asked if he knew a young medical student who had catalogued a small implement collection there.

Koslow knew him well. It was he. And for the next few months, the surgical resident spent the miniscule hours of free time he was able to budget each week at identifying the wide array of often gruesome, sometimes beautiful, and occasionally puzzling tools.

Using a skill picked up on vacation trips, Koslow photographed—using a light box and the advice of Medical Center staff photographers—each item for additional cataloguing.

"I consider myself more of an historian than a collector in that I get as much joy from cataloguing and working with someone else's as I do from my own collection."

Koslow, an admittedly addicted collector, does maintain his own small medical artifacts collection and also, as a hobby, collects stamps—all with medical themes.

"Just about everything I do is medical," laughs Koslow.

The painstaking work for Koslow at Lane Library involved matching various implements with various catalogues, many of which were in the Lane collection.

"What you do is you look back a year at a time until the particular item isn't there anymore. Then you figure it was introduced the next year, and that's often how you date objects," he explained.

Storing data mentally is a crucial skill for the cataloguer.

"There was one particular scissors, I just couldn't identify," said Koslow. "I just kept it in the back of my mind until one day I ran across it in a catalogue."

-more-

3-3-3

While the the collection as a whole, Koslow estimates, is worth about $500,000, individual implements are worth from about $5 to $300, while several large surgical kits range in value up to about $6,000.

"Those came from a day when the surgeon had to supply his own tools. The cases were ornate and the doctor carried it around from operation to operation. Before sterilization became a common practice in the last decades of the 19th century, the knives often were simply wiped off and put back in their crushed velvet container, where an often deadly array of germs waited on the metal to be inflicted into the next patient.

"We can learn a lot about medicine by looking at these knives," said Koslow. For example they would make double-sided knives, "so in an amputation they could go around first one side and then without turning the knife, they could reach around and get the other side.

"Speed was essential in the days before anesthesia, because of the humane need to finish as soon as possible to reduce the patient's suffering."

While many of the devices, including the scarifiers, are testaments to outdated and now rejected practices, the collection includes several precursors of hope.

Among these are two listerizers, looking a bit like kerosene lamps, which were used to vaporize carbolic acid as a disinfectant. Starting around 1870, these devices were the first major breathrough in surgical infection control and drastically reduced deaths.

From the 1840s comes a trephine set, used to drill holes in people's heads to release "evil humors" from the brain.

While the superstitious practice, which originated in prehistoric times, is of course extinct, the technique has been adapted to modern day surgery. Doctors occasionally cut a hole in the skull to release the pressure of blood or water on the brain.

As for Koslow, he is taking two years off after his third year of residency to pursue a two-year research project in Bethesda, Maryland under the auspices of the American Red Cross.

He is researching early signs in the development of hardening of the arteries, and he hopes after the project and two more years of residency to practice vascular surgery—and continue collecting.

STANFORD—

Dr. Michael Eliastam, director of Stanford University Hospital's Department of Emergency Services, has been named to three new administrative posts in the Hospital and the Medical School by Dr. Lawrence G. Crowley, vice president for medical affairs.

Eliastam, 37, will continue as medical director of Emergency Services, while dividing the remainder of his time among the three functions, which include serving as faculty consultant to the Hospital Modernization Project; acting as deputy to Dr. James Silverman, Hospital chief of staff; and advising Vice President Crowley on legislative matters.

As associate director of the Stanford University Hospital Modernization Project, Eliastam will serve as the primary liaison between the Project staff and both faculty and community physicians.

In his role as deputy chief of staff for the Hospital and assistant dean for clinical affairs, Eliastam will be involved with patient care activities of medical staff and house staff physicians, and the interface between physicians and Hospital administration.

As special assistant in the vice president's office for legislative and related affairs, Eliastam will be concerned with state and federal changes in legislation likely to affect the practice of medicine.

A member of the Stanford Medical School faculty since 1974, Eliastam has just returned from a year-long leave of absence during which he was a visiting scholar at the National Center for Health Care Technology (NCHCT) in Rockville, Maryland. As special assistant to the director of the NCHCT (a division of the federal government's Department of Health and Human Services), Eliastam concentrated on medical technology assessment issues.

Eliastam's previous training and experience combine interests in medicine and public health policy.

He has been director of Emergency Services since 1974.

A native of South Africa, Eliastam received his M.D. degree from the University of Witwatersrand Medical School in Johannesburg in 1966. He completed his medical and surgical internship and residency training in Johannesburg and at Rush Presbyterian St. Luke's Medical Center in Chicago.

Eliastam earned masters' degrees in public administration and in public policy from Harvard University in 1972 and 1973. His research activities have been in the areas of paramedic care in the field, and the cost effectiveness of x-rays in the emergency setting.

STANFORD—

Dr. Henry S. Kaplan of Stanford University School of Medicine will be awarded a Gold Medal for distinguished achievements, at the American College of Radiology's (ACR) annual meeting in Las Vegas on September 23.

Kaplan, D'Ambrogio professor of radiology and director of the Stanford Cancer Biology Research Laboratory, in the 1950's conceived the use of high energy linear accelerators in radiation therapy for cancer patients, a technique that has since been used with highly successful results not only at Stanford Medical Center but in cancer centers and hospitals throughout the world.

Kaplan's pioneering work in radiation therapy techniques as well as in diagnosing stages of cancer for planning treatment strategies, has led to dramatic strides in treatment of patients with Hodgkin's disease and other cancers of the lymphatic system. As a result, today Hodgkin's disease is one of the must curable cancers.

The Gold Medal is awarded annually by the ACR, an association representing more than 17,000 physicians who specialize in radiology, to one or more radiologists who have made distinguished contributions in the field.

Receiving a Medal along with Kaplan this year will be Dr. Seymour Ochsner, of the Ochsner Clinic in New Orleans, Louisiana, the ACR said in announcing the upcoming honor.

Kaplan, who has been on the Stanford faculty since 1948, received his B.S. from the University of Chicago and his M.D. from Rush Medical College in Chicago.

An internationally respected authority on cancer and radiotherapy, Kaplan is the recipient of numerous other honors, both national and international.

(Editors: Photos of interns at work available on request)

STANFORD—

They are doctors, they are students, and each year around this time many of them are new. Their first assignment can be to save a life.

"They're somewhere between a student and a trained physician," says chief of staff Dr. James Silverman of the approximately 410 house officers contracted to Stanford University Hospital.

These interns and residents are here to learn, yet they are paid and are sometimes given the responsibility of life and death.

Faculty members and administrators often say the hospital could not be run without their help, and the logistics of their scheduling tend to support this.

Starting dates for the new crop of house staff are staggered over a 10-day period.

First come the surgery interns, June 21, followed three days later by pediatrics and a day later by medical interns. Then on July 1, the residents who have completed their service depart after giving the new doctors a five to ten day orientation.

"It is scheduled it this way to make it as minimally disruptive as possible," says Helen Rantz, who since 1967 has directed the House Staff office serving Stanford and the hospitals affiliated with its house staff program—Veteran's Administration, Santa Clara Valley Medical Center, Kaiser Hospital in Santa Clara and Children's Hospital at Stanford.

While each of the new interns, sometimes called a first-year resident, works under supervision of a resident, faculty member or community attending physician, the responsibility for split-second decision making on vital matters comes very quickly.

Bonnie Maldonado, a pediatrics intern assigned to Children's Hospital, said vital responsibility started her first night on call.

"A child was brought in with acute asthma. The resident was admitting a leukemia patient and would have come over had I needed him. But she was busy, so with the help of the nurses, I ordered medication" and took the child through to the admitting stage, said Maldonado. "He's okay, and he's going home soon."

John Cameron, who like Maldonado attended Stanford Medical School and moved straight into an internship here, works in East 1B where he cares for private medical patients.

"There is a lot of responsibility, especially on night duty, when you have to reach the attending physician on the phone. There's always help available, but there are a lot of decisions you have to make."

The work schedule for interns and residents is stiff with most of them drawing every third or fourth night on call. Some services are more hectic than others, and at particularly busy departments, such as medicine, the house stasff member might need to be up nearly the entire period of each on-call shift.

The hectic schedule is nothing new, says Rantz, who has been associated with doctors and housestaff most of her adult life. She was engaged to an intern who was later to become her husband, the late Dr. Lowell Rantz, former associate dean for clinical affairs at Stanford.

This year she processed 68 interns and 75 residents arriving at Stanford to further their education. While much of their schedule—including grueling hours and increased responsibility—are standard over the years, she has noticed that trends in recent years which have made coping as a house staff member somewhat different than in her husband's time around World War II.

"For one thing the housing situation, particularly here, is grave. We don't see as many married house staff any more. The cost of housing in this area makes it very difficult.

"So many of these people are doubling up or paying far more than their salaries would allow for housing."

—more—

2-2-2 The salaries or educational stipends which house staff receive seems generous by standards of several decades ago, when house staff pay may have been several hundred dollars a year. Rantz herself considers the pay, starting at $18,040 for Stanford Hospital interns, "rather generous, at least considering it was $8,000 ten years ago and $12,500 five years ago."

But she notes that many years ago, house staff members were provided with lodging and food in the hospital. They weren't forced to fend for themselves in a harsh economy.

Silverman agrees that housing is a serious problem and often increases the emotional toll felt by the spouses of housestaff members.

"What sometimes happens is that the resident won't find a place to live nearby. So he'll rent a tiny place a half hour or more from the hospital, and he'll leave his wife at home alone while he comes to work in the family's only car."

Subsidized or otherwise inexpensive housing near the hospital is seen as critical by Silverman if Stanford is to retain the highest quality house staff.

Already, notes Dr. Irving Schulman, chairman of the department of pediatrics, some house staff members are choosing to serve at other institutions where the cost of housing is less.

"We really have no way of telling how many people this affects. And I do think it's part of a national trend toward people staying closer to home where they're settled because the cost of relocating is so high.

"But when we've followed up in some cases, we have found highly qualified applicants who have told us they have selected other institutions in areas where the cost of living is lower."

Nevertheless, the competition for an internship or residency at Stanford remains stiff.

Schulman says he's pleased with the present crop. Over the years, he says, "the interns change as the student population in general changes.

"The ones in the '60s were different. They carried the same social concerns as the rest of the population their age with broad interests away from medicine."

Today's interns, he believes, generally direct their attention more exclusively toward medicine.

But house staff and doctors have other reasons for focusing exclusively on medicine. The grueling schedules, and Silverman says the often small circles which today's specialists in training spend their time sometimes produce an isolation which can interfere with their ability to function as total people.

"What you have, particularly in a university type setting, is radiologists who talk only to radiologists, orthopedists talking only to orthopedists," Silverman said.

More cross-pollination of disciplines and ideas, he said, would be desirable.

Yet the pressures of learning and dealing with patients remain, and Rantz says despite the changing trends, interns and residents over the years have remained a hard working group by need and dedication.

Most of the interns accept the grueling schedule, which often require 24-hour days throughout a five-year commitment.

But some of the newcomers are questioning the grind as it relates to patients.

"Last night I had one hours sleep, and there is no way I can be as alert for my patients today as I might otherwise," said Maldonado. "The schedule, not to mention the effect on me, must take its toll on patients, and that's not a good thing. Maybe that's part of the reason some physicians turn out cold. They just don't have enough time and energy always to deal with their patients as human beings.

Orientation is sometimes an awkward process, says Bill Benitz, senior resident in pediatrics.

"This year we've tried to have some orientation sessions. One of the things we've tried to generate is an attitude of teamwork. For example, we stressed the need to to treat nurses as colleagues and not just someone who is an employee. After all at the start of training the nurses really do know some more things than the intern."

Many, if not most, of the interns realize their rather raw status as doctors. Asked how she felt being called doctor, pathology intern Sara Michie replied humorously:

"Nobody around here calls you doctor when you're just starting out."

FOR IMMEDIATE RELEASE

STANFORD—

The central campus area of Stanford probably will be sprayed with malathion droplets during the coming week, but no definite schedule has been set, Medfly Project officials reported Tuesday afternoon, July 21.

Aerial spraying in the so-called "San Mateo zone" north of Page Mill Rd. could start as early as Thursday morning. But no firm schedule has been set.

As of 9:30 a.m. Tuesday, the Stanford Hospital Department of Emergency Services reported no patients had been received with malathion-related health problems or complaints since the spray program started last week.

The Hospital's Nursing Department reported its staffing remains at an average level. While five or six pregnant women who asked for time off specifically mentioned they were leaving the area because of spraying, the total number of people asking for sick leave has not been above normal.

The Medical Center's special phone line (497-5000) with a taped message on health precautions, updated regularly as new information is obtained, has received more than 180 calls a day.

Once the spraying schedule is known, Prof. Robert Schimke, head of the Biological Sciences Department, says, "we're going to close the vents and hope for the best." Several projects inside the building could be affected by malathion.

At the Medical Center, all air intakes have filters sufficiently dense to screen out malathion droplets. As a prudent precaution to further minimize risk, the Medical Center is installing filters that will exclude particles larger than 0.3 microns in diameter in certain air intakes. Malathion droplets measure 800 microns across.

As an extra measure, the ventilation system will be turned off temporarily during spray periods, if they occur in the immediate area.

Crews organized by Grounds Manager Herb Fong have stripped primary medfly host plants of their fruit throughout the central campus area, including student housing.

More than 60 students volunteered to help strip fruit. This effort was coordinated by students Susan Shepherd and Barbara Hecht at Escondido Village.

University crews picked up bagged fruit voluntarily stripped in the faculty-staff housing area.

Four members of the Salinas media were the guests of honor at a Stanford luncheon this week (July 13) where they received certificates for their participation in the Stanford Heart Disease Prevention Program (SHDPP).

The awards were in appreciation to the men for broadcasting Program information in Spanish to the Mexican-American Community in the Monterey-Salinas area.

"Unless you have a newspaper column or a news broadcast nothing can happen for a program like this," said SHDPP Chairman John Farquhar, who presented the certificates. " You build on that stong foundation."

Media leaders honored were Tony Trevino and Martin Kline both of radio station KCTY, Salinas; Armando Guzman of KSBW television channel 8, Salinas; and Oscar Parodi of Salinas' El Sol newspaper.

The-year-old program is a mass education and prevention plan against heart disease in the Monterey, Salinas, and Pacific Grove communities.

STANFORD—

There was a time when a housekeeper's training consisted of the simple command: "Get rid of the dirt!"

Not anymore. Nowadays, like everything else affected by modern technology, institutional housekeeping has become complicated business.

Especially in places like hospitals, explains Maria Sosa, daytime area coordinator of Housekeeping at Stanford University Hospital. Says Sosa, who supervises five supervisors, "You have to really teach your employees to be very careful—especially in critical care areas."

The National Executive Housekeepers Association, Inc. (NEHA) is one organization that helps spread information on recent advances in the field. NEHA provides housekeeping management staff with a 320-hour educational program of courses in sociology, psychology, economics, management, communications, safety practices, environmental controls and more.

Sosa and six fellow members of the Hospital's housekeeping staff recently completed the program, qualifying to apply for certification as members of the association.

Karl Hickethier, executive housekeeper of the Hospital, is himself a certified member (he and three others previously completed the program). Eligible employees wishing to participate, he explains, are awarded educational leave time to do so. They are paid regularly and reimbursed for tuition costs.

Hickethier recognized early the need to keep in step with ever-changing requirements of the job. It's been largely through his efforts, in fact, that Stanford staff are joining NEHA. Recalls Sosa, "Karl encouraged us to take this opportunity for our own good."

Housekeeping is like any other field, she says, in that higher positions demand increasingly higher standards and credentials.

Agrees Donald Utt, associate administrator of the Hospital, "This program qualifies the employees for promotion. And certification is really a recognition of their skills."

Several years ago, he says, the Hospital began to send housekeeping staff members out of town—to the mid-west or the east coast—in order to attend the program. Sosa and her colleagues completed their first 160 hours during an intensive month in Oklahoma four years back.

Luckily for westerners, though, since March of 1980 the program has been sponsored at U.C. Santa Cruz. The courses, three full days apiece, are given at the Veterans Administration Hospital in Palo Alto.

NEHA's members include housekeeping management staff from hospitals, nursing homes, hotels, motels, schools, industries, department stores, office buildings, recreation centers and parks. They concentrate on seeking housekeeping improvements that are both effective and economical.

And they look for new members. Sosa, now ready to apply for certification herself, intends to help in active recruitment efforts as soon as she's officially on board.

STANFORD—

Stanford University Medical Center will reimburse Medicare approximately $1.5 million as a result of adjustments on the Medical Center's cost claims for services rendered by Stanford faculty physicians to Medicare patients for the years 1975 through 1977.

A report issued June 29 by the Department of Health and Human Services Audit Agency in San Francisco approves adjustments proposed by Stanford's Medicare intermediary, Blue Cross of Northern California, and clarifies principles to be used by Stanford in preparing annual cost claims for faculty physicians' indirect services to Medicare patients.

The principles are the same as those agreed upon in January 1979 by Stanford and the California Department of Health Services for services provided to Medi-Cal patients.

These reimbursement principles, applied retroactively, lower by about $1.5 million the cost claims Stanford submitted to Medicare for the three year period, 1975-1977, during which Medicare's total cost reimbursement to Stanford was approximately $58 million (an adjustment of about 2.6 percent.)

Stanford has been using these principles to prepare its cost claims since 1978 so no further adjustments for this issue are anticipated.

After concluding the agreement with Medi-Cal in January 1979, Stanford brought the Medi-Cal settlement to the attention of Medicare officials in March of that year, believing that the same agreed upon cost reimbursement principles would apply to the Medicare program as well.

Dr. Lawrence G. Crowley, vice president for medical affairs and acting dean of the School of Medicine, said that Stanford is pleased that the reimbursement issue with Medicare now has also been resolved.

"The present agreement with federal officials is entirely consistent with the principles of reimbursement that were agreed upon back in 1979 with California's Department of Health Services for Medi-Cal," Crowley added.

Under Medicare law, teaching institutions may recover costs, on an annual basis, for indirect patient services provided by faculty physicians to Medicare patients. Such services include medical administration, medical direction, and supervision of the services rendered by interns and residents.

The principles settled in the Medicare agreement, as with Medi-Cal, cover these areas:

- faculty patient care efforts are determined by use of an effort report prepared by the individual faculty members;
- direct medical and surgical professional services to Medicare patients are reimbursed through payment of a professional fee;
- indirect faculty effort towards providing professional services to Medicare patients are paid for by Medicare to the institution through the hospital cost reimbursement system.

Crowley said that, following the Medi-Cal settlement, the Medical School anticipated a similar adjustment would be agreed upon with Medicare and the School established reserves to pay back the amount claimed by Medicare for the three year period.

STANFORD—

This information is being provided as a community service by Stanford University Medical Center. It will be updated as further guidelines are received from state authorities. These recommendations are based on data from a report of the California Department of Health Services which states, "there is no significant health risk involved in the proposed aerial application of malathion."

During spraying:

— stay indoors, and close windows. Avoid pulling air into house through fans or air conditioner. This also applies to automobile travel.

For the duration of the Medfly project and after each spraying, the following is advised:

— Avoid contamination of your home by washing exposed areas of body, wiping feet or leaving shoes at the door.

— Infants and children should also be washed following exposure and according to usual cleanliness habits.

— Food exposed to spray should be washed before eating.

If a woman is known or suspected to be pregnant, (particularly in the first three months of pregnacy), since it is not known if long term risks exist, we recommend she follow the above advice and also stay indoors the day following spraying if possible.

The above recommendations are prudent guidelines based on available information. Past spraying experience with malathion suggests that health risks are small.

STANFORD-SEVEN MILD CASES OF HEPATITIS A WERE CONFIRMED BY LABORATORY TESTS THURSDAY AMONG THE 450 PERSONS ADVISED IN JUNE BY STANFORD UNIVERSITY MEDICAL CENTER TO SEEK GAMMA GLOBULIN TO PREVENT THE DISEASE.

IN ADDITION; KAREN AXNICK; INFECTION CONTROL SUPERVISOR AT STANFORD UNIVERSITY HOSPITAL; SAID BLOOD TESTS WERE PENDING ON FOUR OTHER PERSONS-ALSO EMPLOYEES OF THE MEDICAL CENTER-WHO WERE BELIEVED TO HAVE CONTRACTED THE DISEASE FROM AN AFFECTED FOODHANDLER.

AXNICK SAID ALL OF THE 11 STAFF MEMBERS HAD DEVELOPED ONLY MILD SYMPTOMS AND SEVERAL MIGHT NOT HAVE REPORTED THEIR SYMPTOMS HAD THEY NOT BEEN WARNED OF THE POSSIBLE RISK AFTER EATING CATERED FOOD.

THE SEVEN CONFIRMED CASES; SHE SAID; WERE ROUTINELY REPORTED TO THE SANTA CLARA COUNTY HEALTH DEPARTMENT.

NO HOSPITAL PATIENTS HAVE EXHIBITED SYMPTOMS OF THE DISEASE AND NONE OF THE INFECTED PERSONS WERE SERIOUSLY ILL OR NEEDED TO BE HOSPITALIZED; AXNICK SAID.

THE ADVICE TO SEEK GAMMA GLOBULIN SHOTS WAS ISSUED TO PERSONS WHO ATE CATERED MEDICAL CENTER MEALS BETWEEN MAY 16 AND JUNE 5 AFTER THE INFECTION WAS CONFIRMED IN THE CATERING UNIT FOODHANDLER ON JUNE 12.

THE EMPLOYEE; A BURLINGAME RESIDENT WHO WORKED AT THE CENTER FOR ABOUT FIVE MONTHS; PREPARED FOOD ONLY FOR CATERED LUNCHEONS AND NEVER HANDLED FOOD GOING TO PATIENTS OR PERSONS EATING IN THE HOSPITAL'S CAFETERIA; SAID JOHN VARNADO; DIRECTOR OF DIETETICS.

THE FOOD SERVICES EMPLOYEE STOPPED WORK JUNE 5 WHEN HE DEVELOPED THE FIRST SYMPTOMS; WHICH NORMALLY ARE FATIGUE; HEADACHES OR STOMACH UPSET.

AXNICK SAID FURTHER CASES AMONG THE GROUP EATING CATERED MEALS WERE POSSIBLE UP UNTIL ABOUT JULY 17; SINCE SYMPTOMS OF THE DISEASE NORMALLY DEVELOP WITHIN SIX WEEKS OF EXPOSURE.

HEPATITIS A IS A VIRUS INFECTING THE LIVER; WHICH INFREQUENTLY REQUIRES HOSPITALIZATION AND ALMOST NEVER PRODUCES LONGTERM DISABILITY. SYMPTOMS; SAID AXNICK; ARE MUCH LESS SEVERE THAN THE MORE VIRULENT HEPATITIS B.

NORMALLY; AXNICK SAID; CLOSE PHYSICAL CONTACT OR INGESTION OF FOOD HANDLED BY AN INFECTED PERSON IS REQUIRED TO TRANSMIT THE AILMENT.

AS A PRECAUTION; DR. THOMAS MERIGAN; HOSPITAL EPIDEMIOLOGIST; SAID THURSDAY AN INVESTIGATION WAS CONTINUING IN AN EFFORT TO LEARN IF THE RECENTLY INFECTED STAFF MEMBERS POSED A THREAT TO OTHERS; INCLUDING FAMILY MEMBERS; HOSPITAL EMPLOYEES AND PATIENTS.

''THE FOLLOWUP MEASURES WILL NOT HAVE TO BE NEARLY AS EXTENSIVE FOR THE RECENTLY INFECTED EMPLOYEES; SINCE THEIR ABILITY TO TRANSMIT THE DISEASE TO OTHERS IS SIGNFICANTLY LESS THAN THE DIETARY WORKER WHO PREPARES FOOD; A MAJOR TRANSMITTER OF THE AILMENT;'' MERIGAN SAID.

THE 11 PERSONS WITH RECENTLY CONFIRMED OR SUSPECTED CASES INCLUDE ADMINISTRATORS; DOCTORS; AND SECRETARIES.

STANFORD—

Gift income to Stanford University Medical School has reached record levels with three months remaining in the fiscal year, a fundraiser said Wednesday (July 1).

For the nine-month period ending May 31, gifts to the Medical School totaled $18.5 million, a 25 percent increase from the $13 million for the same period a year ago, said John Ford, director of medical development. The nine-month figure has already surpassed the previous record of $16.5 million for a 12 month fiscal year, set three years ago.

A total of 2,796 living individuals gave $6 million, Ford said.

"One major reason for this encouraging rise," said Ford, "is that we have two compelling projects which have attracted interest and support."

A cardiovascular research building generated gifts totaling $3.7 million, including $2.8 million from an anonymous donor. Last year, a gift of $4 million from the Max C. Fleischmann Foundation of Reno initiated the fund drive for the building.

The 30,000 square foot facility is expected to be completed in about two years. It will house the research and academic programs of cardiology, headed by Dr. Donald Harrison, and cardiovascular surgery, including Stanford's well-known transplantation program led by Dr. Norman Shumway.

About $2 million of the $14 million gift total still needs to be raised for the building, Ford said. All of the money for the center is expected to come from gifts.

The second project is the renovation of the Boswell Clinics, the primary outpatient treatment facility at the medical center. The James G. Boswell Foundation of Los Angeles gave $2 million for the project during the current fiscal year. The foundation gave an initial $1 million five years ago.

All except $600,000 of the $4.6 million needed for renovation is to come from gifts. The balance is slated to come from fees and other clinic income.

Renovation is scheduled to begin this summer and is expected to be completed in stages during the next few years, according to Mary Lou Kilcline, a Medical Center administrator.

Ford noted that many faculty members have been particularly active in support of fundraising during the year.

Shumway and Harrison, for example, participated in many events in support of the cardiovascular building, and faculty-initiated, industry-affiliated programs in the Department of Biochemistry and Medicine have generated unrestricted gift support for those departments.

"With the present budget climate in Washington," says Ford, "our faculty have shown great initiative in seeking private research funds to pick up any decrease in federal funding."

Business, industry, foundations and associations are a crucial source of funding for the Medical School and Stanford as a whole.

During the current fiscal year, in the business and industry category, 151 donors gave $1.8 million, 54 foundations offered $4.6 million and 47 associations gave $1.3 million.

Twenty bequests accounted for $5 million, and about 30 percent of the Medical School's living alumni gave $250.000. Ford said.

STANFORD—

Thirty-four new graduates of the Stanford-Foothill Primary Care Associate Program stepped forward last week to receive their certificates of clinical proficiency as physician's assistants and family nurse practitioners.

The ceremony, which was held in Grant Courtyard of the Medical School, marked the end of a vigorous two years of training for these young people, said Victoria Demartini, student affairs coordinator.

The program, she explained, is based on a dedication towards medically underserved populations, among whom many of the trainees have lived or worked. And most intend to return, carrying new skills and knowledge to places their services are most needed.

The physician's assistants are now ready to practice in conjunction with physicians. They have been trained to do physical exams, take medical histories, assess and manage common acute and chronic medical conditions, treat wounds, and provide health education and counseling.

An underlying purpose of the program was well articulated at the Friday ceremony by guest speaker John Vasconcellos, when he said, "There has been a shift in our society recently, to recognizing that there are many different levels of primary health care and various kinds of training appropriate for providing responsible and skillful health care services."

Vasconcellos is an eight-term assemblyman representing the twenty-third district in the California legislature. He was invited to speak at the graduation, said Demartini, because of his efforts to promote legislation in the health field.

Program director Virginia Fowkes, also speaking at the ceremony, commented to the audience of graduates and their families, "Since this is a relatively new form of health care delivery, the eyes of the nation are upon you as you make your way into communities, and into practice."

The Primary Care Associate Program, which graduated its first class in 1973, is a training course that Stanford runs jointly with a consortium of community colleges around the state, including Foothill College in Los Altos, Hartnell Community College in Salinas, Modesto Junior College, Bakersfield Community College, and College of the Redwoods in Eureka.

The program is currently government-funded, and tuition-free for legal residents of California.

Trainees spend their first year in pre-clinical classroom work at one of the participating colleges. During the second year they carry out clinical work, coordinated through Stanford University Medical Center and consisting of didactic and clinical teaching at Stanford as well as preceptorship training with a physician in the community.

STANFORD—

A joint Stanford-federal program, which during the past decade tapped space agency expertise to produce several significant developments in medical care, is to be disbanded at the end of the year.

The demise of Stanford's Biomedical Applications Team (BATeam) may seriously cut off or eliminate the ability to transfer National Aeronautics and Space Administration knowledge to civilian medical applications, say several federal authorities and Stanford personnel.

"It's going to interfere with the transfer of a lot of technology that we have had access to and curtail monitoring of activities here that NASA has had available," said Dr. Donald C. Harrison, chief of the division of cardiology and executive director of the BATeam.

"This loss of funding is the culmination of what amounts to a fairly long decline in NASA's budgeting for us, and I think in NASA's longterm devotion to technology utilization," said Harry Miller, administrative manager for the Division of Cardiology, who helped set up the BATeam 10 years ago.

Since its inception, the BATeam has developed a talking wheelchair, a safe device to monitor brain pressure in head injury patients, and magnetic measurement devices which allow doctors to monitor complex cardiac defects without the danger of inserting chemicals or mechanical probes into the heart.

Stan Miller, technology utilization officer at NASA's Ames Research Center in Mountain View, said the teams nationwide were "being phased out as part of the continuing belt-tightening that NASA has had to face."

The Stanford BATeam, which worked closely with nearby Ames, was a year ago one of seven similar technology transfer groups. Since then, five of the teams were eliminated or, like Stanford, being phased out this year.

The Stanford group, said local BATeam director Gary Steinman, has received $50,000 in funding from NASA to allow the team's three full-time and five part-time employees to wrap up loose ends by Dec. 31.

The team was headed since its inception by Harrison, who along with Harry Miller founded the team as an offshoot of existing research in the Division of Cardiology. Both men continue to serve as part-time officers along with their cardiology duties. Steinman, biomedical engineer Luke Brennan and secretary Margo Ballamy are the full-time employees.

Another BATeam currently is operating at Research Triangle Institute (RTI) in North Carolina. The other remaining technology transfer team, concerned primarily with transportation applications, remains at SRI International in Menlo Park, Calif..

Ray Whitten, acting chief for terrestrial applications at NASA in Washington, said RTI's and SRI's groups were the two teams chosen to continue "because they are the two oldest. These teams have a broader perspective. And since we are phasing out, we thought these teams would be the best to do that," he said.

The Stanford team, said Harry Miller, has been funded during the past 10 years at up to $265,000 per year. Last year's funding was $200,000.

more

Essentially, Whitten explained, the teams acted as brokers, identifying civilian problems and then seeking solutions within the vast bank of data NASA has collected over the years from its space program.

While many of the other teams contracted out the actual research, Steinman and Miller noted that Stanford was uniquely able to do its own research in a variety of clinical and laboratory settings within the university.

Harold Sandler, chief of the biomedical research division at Ames agreed that the loss of a research institution as a team sponsor was significiant.

"With the demise of active participation of medical groups, of which Stanford represents the best that NASA has at this time, the reliance for medically based transfers are going to fall on the industrial community, because as I understand it, we are going to function with RTI being the main interface between the medical community and NASA. The way in which they will work would be to try and be aware throughout the medical system and then broker ideas through industrial channels to the medical community, rather than trying to work with the medical community directly.

"...I believe that would constrict the potential of usable information to transfer to less than a quarter of what would be possible otherwise, since there is no company that is going to be willing to risk an investment until they have some preliminary evidence that something is worth investing in. And all the easy things have been pretty much covered."

Other medically oriented BATeams (as contrasted with the other technology transfer teams) had existed in the past decade in Houston, Denver and most recently, the University of Wisconsin.

Regarding the team approach in general, Whitten added:

"Since the early 1960s, "it's been pretty well proven that without a catalyst, without somebody moving between technology development and technology needs, the transfer didn't take place."

Stanford's Miller said, "Our mission for NASA as it's been stated in the last few years is to identify important medical problems that are amenable to technological solutions.

"Then we try to identify NASA technologies which might be uniquely applicable to solving the problems, adapting that technology and evaluating the resulting application to see if it can be commercialized," Miller said.

Commonly, said Miller, Stanford makes its technology available for nonexclusive production to commercial firms. In the case of the talking wheelchair, Children's Hospital at Stanford, which participated in the development, holds a royalty free license, which is to be issued to a Huntington Beach firm—Computers for the Physically Handicapped—for production.

The device, will enable wheelchair patients unable to speak, to write statements on a keyboard which will be vocalized by a speaker on the unit.

The device is programmed to translate written language into a variety of synthesized sounds and can be readily reprogrammed into languages other than English.

Whitten pointed to the talking wheelchair, or versatile portable speech prosthesis, as one of two of the outstanding technology transfer developments to emerge from the Stanford team.

The other, he noted, was the intracranial pressure (ICP) monitoring system for neurosurgery patients requiring continuous monitoring of pressure on the brain. A small transmitter is inserted in the skull between the scalp and the exterior of the brain sac.

The equipment overcomes several earlier problems with pressure monitoring devices in that it requires no awkward permanent transmission lines and does not require the brain sac to be punctured, which poses a risk of injury and infection.

-more-

3-3-3

NASA's Sandler said the ICP device offers an outstanding opportunity for widespread use and could eventually be used extensively and routinely for such occurrences as motorcycle accidents.

The brain pressure measuring device was adapted from the technology used to measure wind pressure on airfoils in a wind tunnel. The transmitter was adapted from biotelemetry instruments used to measure the medical condition of astronauts in space.

"It required a lot of creative insight to come up with this new application from the two seemingly unrelated technolgies," Whitten said.

The device is to be manufactured by Pacesetter Systems Inc. of Sylmar, Calif., under a nonexclusive license. Stanford will make the technology available without royalty fees but with the understanding that other companies wishing to manufacture the device will be given the same rights.

Stanford has additional contracts with NASA which will not be affected by the BATeam breakup, and some ongoing projects, such as the talking wheelchair, are developed far enough that they will continue under other auspices.

But Miller said further development could be impeded by the cutback. NASA's Stan Miller said his agency would still make information available to civilians, but he added, "It will be more difficult to get these ideas pried out."

And NASA's Whitten said, "What we're going to try and do is continue the technology transfer. But it will be harder without the teams. The teams formed a very important brokerage role."

Nationally, he explained, the teams were budgeted for some $1.1 million per year with about 85 projects in various stages of development. The funding level, he said, enabled NASA to comply with the federal technology innovation act of 1980, which requires that .5 percent of research and development budgets of agencies such as NASA be used for technology transfer to civilians.

He said it is unclear whether his agency will be in compliance after cutbacks in the technology transfer program are completed next year.

STANFORD—

White inmates in a California youth prison behave with more hostility toward other ethnic groups than blacks or Mexican-Americans, two Stanford University psychiatrists have concluded.

Moreover, their study showed white inmate leaders tend to be more hostile toward other groups than their followers, while blacks and Mexican-American leaders were more tolerant of different races than other members of their ethnic group.

The study by Dr. Adolf Pfefferbaum and Dr. Norman I. Dishotsky was published in the August issue of the *American Journal of Psychiatry* and was based on field work at a California Youth Authority center.

Pfefferbaum said the study appears to be most significant because it calls into question a popular notion that individual personality is the sole determinant of prejudice.

"We didn't want to challenge the notion of personality as a factor in prejudice, but what we did find was that social factors—including relationships within a peer group and incarceration—were important in determining race relations," Pfefferbaum said.

Of 1,000 wards at the center, 350 were identified by ethnic group and categorized as leaders or followers. The study group included 151 whites, 104 blacks and 65 Mexican-Americans aged 16 to 21.

Each ward was rated by five supervisors, whom were asked the question, "How does the ward relate to his own and other ethnic groups?" The supervisors were told to categorize each youth's racial hostility on a five-point scale with one indicating cooperation, five indicating maximum hostility.

Among the whites, leaders averaged 3.0 in their attitude toward blacks, while their followers tended to be more tolerant toward blacks with an average score of 2.6.

In contrast, black leaders were more tolerant than their followers toward whites, scoring 1.9 for the leaders, 2.3 for the followers. Mexican-American leaders scored 2.0 toward blacks, significantly more tolerant than their followers who averaged 2.7.

The figures, said Pfefferbaum, tended to question another common notion: that prejudiced people are unselective in their hatred of other groups.

The study showed that while blacks and Mexican-Americans tended not to distinguish in their feelings of cooperation between each of the other two groups, whites were signifcantly more prejudiced toward blacks than toward Mexican-Americans.

White leaders scored 2.6 in their feelings for Mexican-Americans, contrasted with the more hostile 3.0 figure in their attitude toward blacks.

Pfefferbaum said that he became interested in the subject of ethnic prejudice among incarcerated youth during a visit several years ago to a facility where he observed some white wards with swastika tattoos and other over symbols of the Neo-Nazi movement.

"What we found," said Dishotsky, "is that their knowledge or understanding of German Naziism was minimal, highly distorted or nonexistent.

-more-

"There is very little indication that there is much potential for a mass movement, but there certainly is a movement within the prison environment. What therefore happens is that people exposed to the prison environment are exposed to a much more racist feeling than the population at large."

Both researchers suggested that major shifts in the prison population during the past two decades—in which the proportion of blacks and Hispanics have grown—have led to the decline in power and status within the American prison system of whites.

This, the psychiatrists said, contributes to a white power backlash.

Pfefferbaum also speculated—but quickly added that his theory was untested—that white youths came from more varied backgrounds and had not been required to think of themselves as part of a a threatened group before entering prison.

On the other hand, Pfefferbaum said many of the blacks and Mexican-Americans may have come from minority communities where a strong sense of group identity and an ethic of mutual protection was strong.

Both psychiatrists suggested that the reasons behind the differing attitudes might be worthy of a future study. And they emphasized that a study was warranted to avoid the major pitfall of studying prejudice—making assumptions without adequate data.

"There isn't an awful lot of stuff written about racism that is data bound. One of the things that we did was collect information and work from that without making a lot of assumptions.

Dishotsky added:

"What we feel we have here is a methodology of measuring racial tensions. And we think that a quantitative method of measuring prejudice in the penal system might help predict where an outbreak of violence might occur in the future.

STANFORD—

The working nurse is target of a new educational program to begin this fall at Stanford University Hospital.

Specifically, the new program is designed for the working nurse without a bachelor's degree, who wishes to earn one while remaining on the job.

Stanford's Department of Nursing Services has joined forces with San Jose State University's Department of Nursing to provide this opportunity. Through their combined efforts, a program—to be housed at Stanford—has been set up as an outreach option of San Jose's already existing program in nurses' training.

Participants in the new program will use packets of self-instructional material to do much of the learning on their own. Classes will be scheduled as often or as rarely as the students and instructor deem appropriate. And the location for meeting will be equally flexible.

Open to all licensed R.N.'s in the community with a satisfactory academic record, the program will be taught by members of the regular faculty at San Jose. Resources and study space will be available at the Stanford Learning Center, almost ready in Suite 327, Nursing Education Services, at 701 Welch Road.

Why has Stanford become involved in this program? To provide nurses with the chance to pursue their training locally and conveniently, according to Julie Shinn of Nursing Education Services, as well as to help in the Hospital's nursing recruitment efforts. "For nurses considering Stanford," she explains, "it's an added advantage."

"What we're providing," explains Louise Trygstad, coordinator for community outreach at San Jose, "is an alternative pathway through the regular program at San Jose, where nursing students begin as freshmen and end up with a B.S. degree. This new program will have the very same outcome for students who are already R.N.'s."

Most prospective students, she says, will have two-year degrees from community or junior colleges. Those accepted into the program will pay a fixed amount per semester in fees, no matter how many courses they opt to take at any one time.

-more-

"How long each student takes to finish the degree will be a totally individual matter," says Trygstad.

Another added attraction for R.N.'s, she continues, is that they may be exempted from taking many of the nursing courses required for other students. This, naturally, is because they have already studied the basics of nursing in order to be licensed by the state.

In order to receive credit for those courses, however, the nurses will still have to pass "challenge examinations," says Trygstad, after studying the course materials available among the program's resources. And all students will have to take the equivalent of San Jose's senior year in nursing, since that is the one leading to the degree after licensure. Senior year's focus, she says, is community health and research.

The program can accommodate as many as 25 students per semester in each center (San Jose is also setting one up at Hartnell in Salinas.) The first session at Stanford will begin in September.

Anyone wishing to apply in time for the next "challenge exams," scheduled to take place in December, should contact Trygstad by the end of September, at (408) 277-2084. But prospective students, she says, should first attend a group advisement session in order to find out more about the program.

The first such session coming up is slated for August 28, at 10 a.m., in room M110 of Stanford Medical School, when Trygstad will be on hand to answer further questions which anyone may have.

STANFORD UNIVERSITY MEDICAL CENTER
News Bureau Stanford, California 94305

FOR INFORMATION CONTACT: Mike Goodkind, (415) 497-6911 or Maureen Roskoph, 497-7105

STANFORD—

A blood center tailored for the often-complex and specialized needs of Stanford University Hospital is scheduled to begin accepting public donors Aug. 25.

The Stanford University Blood Bank at 800 Welch Road is set up to handle about 65 donors daily, said donor recruiter Maureen Roskoph. Previously, the location housed only the bank's administrative offices, but the newly opened facilities contains not only donor facilities, including adjacent free parking, but also a processing lab.

"All of our blood stays in the community," Roskoph said, "and that means each donor is assured that he or she is helping a member of this immediate area."

Although Stanford Hospital conducts extensive research, Roskoph emphasized that all blood is used by patients, unless the donor is informed in advance that his blood is required for research.

The center is equipped with specialized equipment, including an irradiator, which is needed to prepare blood for heart transplant patients. Also in use is a central alarm monitor system, which lab supervisor Teri Lawrence said is unique among California blood banks.

Six temperature sensors in blood storage areas are connected to the machine. Whenever the temperature starts moving away from the optimum temperature for blood storage, an alarm is sounded.

The lab and storage facilities are new. Previously, Roskoph said, all lab work was performed in the hospital's transfusion service work area. The facility at 800 Welch Road previously housed only the blood bank's offices.

-more-

The donor center is open 8:30 a.m. to 8 p.m. on Tuesdays; 8:30 to 6 p.m. on Wednesdays and Thursday; 8:30 to 3:30 p.m. on Fridays and 9 a.m. to noon on Saturdays.

The center is closed on Monday, when the crew will be accepting donations as they have in the past at Stanford University Hospital. Mobile crews will continue to visit various industrial and other locations in the community by invitation on weekdays, Roskoph said.

Appointments are preferred at the new center, which features three beds for regular donations, as well as a bed for pheresis donations, the selective drawing of particular blood components needed for a specific patient.

The Stanford blood bank is a member of the American Association of Blood Banks. Donors, who may give once every 56 days, are entitled through the association to receive one unit of blood without replacement fee for themselves or anyone they designate for a year for each unit they donate.

The replacement fee is a charge above the amount ordinarily paid by insurance companies as an inducement for people to give blood. The Stanford blood bank does not charge such a fee for its own blood, but does assess the fee for supplementary units purchased from other banks.

The Stanford University Blood Bank was established in 1979 after officials determined that the university needed to operate its own facility, because of unique medical and research needs, including the organ transplant program, treatment of leukemia, and disorders of the immune system.

A contract between the university and the American Red Cross to operate a blood bank in Stanford Industrial Park expired at the end of 1979.

STANFORD—

Dr. Robert Hill, chief of medicine at Palo Alto Medical Clinic, was recently elected president of the Stanford University Hospital Medical Staff.

As president Hill will serve for two years and assist chief of staff Dr. James Silverman with such administrative tasks as committee appointments. In addition, he will represent the medical staff at Hospital staff meetings.

A clinic partner since 1958 and a member of the Hospital staff since 1956, Hill is presently on the board of directors of Community Physicians for Patient Care.

This organization of local private doctors was formed in 1978 in action against restrictions placed on them by Stanford Hospital.

Hill was chosen by the active medical staff members for his past membership on such panels as the By-Laws committee, the Joint-Conference committee and the Medical Records committee. He also is a seven-year member and past chairman of the Patient Care Evaluation Committee.

In addition Hill has served as chief of the former Palo Alto Medical Staff and twice as a member of the Stanford Medical Board.

He received his undergraduate degree at Drake University in Iowa and his M.D. at the Indiana School of Medicine in Indianapolis.

FOR IMMEDIATE RELEASE

STANFORD—

A Stanford surgeon has cited a 1975 faculty study as evidence the University covered up possible fraud in medical research by a faculty colleague.

The University has denied the charge, which comes from Dr. Eugene Dong, a self-described "whistle blower" engaged in a complex, bitter and continuing legal controversy since 1979 with Dr. Zoltan Lucas and Stanford.

Both are tenured associate professors of surgery. None of the allegations involve patient care.

Responding to Dong's charges in a brief filed with the California appellate court, attorneys for the University quote the 1975 study as concluding that "the question of fabrication and fraud (by Lucas) is unresolved." The court has upheld the University's contention the report itself should remain private.

Documents recently filed with a petition for a rehearing on discovery issues in the two-year-old case indicate Dong has obtained a copy of the report, but not through University officials.

In an interview, Dr. George Feigen, who headed the 1975 study, said the committee found probable cause to further investigate Dong's allegation of fraud by Lucas but did not "sit in judgment" on the case.

Feigen said he was "upset" at the "inadequate" response to the committee's recommendation that hearings be held on Dong's charges.

While no hearings were held, "I don't think the University covered up fraud," he declared.

"The machinery kind of creaks and groans. It's unfortunate that this carried on so long, but I don't construe it as a coverup," Feigen said, particularly in view of subsequent disciplinary action by the University against Lucas.

Lucas was publicly reprimanded by Stanford President Richard W. Lyman in March 1979 and suspended without pay for 12 weeks for professional misconduct in his research. Lucas admitted that 18 citations of his scientific papers were in error between 1967 and 1977.

One of two research grants Lucas held from the National Institute of Health in 1979 expired last year. The other will end in December. Lucas has requested a leave effective Oct. 1.

* * *

In 1973, 1975, and 1977 Dong raised questions concerning Lucas' work.

Three different internal groups were established to investigate Dong's claims. Counterclaims by Lucas against Dong were reviewed by the Dean's Office and it was determined that no action against Dong was indicated.

The University has consistently sought to maintain the confidentiality of all these internal reviews, a position basically sustained by the state appellate court.

In his current suit against Lucas and Stanford, Dong alleges that the University kept him "in the dark" about the Feigen committee's findings and "lied" to him and the public about what these investigators thought of his allegations against Lucas.

To support his claim, Dong includes a copy of the committee's letter to former Surgery Department Chairman James Mark in October, 1975, recommending further investigation of the charges against Lucas.

-more-

Besides Feigen, the committee included Prof. Leonard Herzenberg, a Stanford geneticist, and Associate Prof. Robert Mishell, a UC-Berkeley immunologist.

In a recent interview, Feigen said he telephoned former Medical Affairs Vice-President Clayton Rich "a couple of times and had a session with him" in person. But Rich indicated there was no appropriate mechanism for further action, according to Feigen.

(The Advisory Board, a group of seven tenured faculty elected by their colleagues, may hold hearings and make recommendations if the University president proposes disciplinary sanctions against tenured faculty members. No sanctions were proposed in 1975. Four years later, there was no appeal to the Advisory Board by Lucas on the sanctions imposed by Lyman.)

Early in 1976, in response to a request from Lucas, the Feigen committee considered additional information from Lucas, circulated to them by Feigen. "This didn't change anyone's mind" about their conclusions, Feigen recalled.

In 1977, further charges by Dong and inquiries from NIH concerning irregularities in Lucas' citations of scientific papers and information provided in his contract proposals triggered an extensive analysis of these documents.

In 10 instances, Lucas admitted papers he cited concerning his research already had been rejected for publication. In five instances, they never had been submitted. In three, the wrong journal was cited.

Dr. John Wilson, associate dean for faculty affairs at the Medical School, and Carol R. Price, associate legal counsel for the University, said there was "persuasive evidence" that five other citations by Lucas concerning his own work were in error.

In his public reprimand of Lucas, based on the Wilson-Price study, Lyman said "There has been no conclusion that your research results have been seriously affected."

But he added: "Because of the chronic nature of your professional misconduct and incompetence over a period of many years, the University must exercise some prospective controls to ensure your behavior in this respect is not continuing."

(In a campus radio interview soon after taking this disciplinary action, Lyman said: "The investigation has been protraacted on this case—too protracted in my view; it has gone on [for] years, and it didn't need to take that long. . . . Faculty are obviously reluctant to bear down on colleagues unless they're really convinced that it must be done.")

In his public reprimand, Lyman said the dean of medicine and head of surgery would conduct a formal review of Lucas' research after two years. This procedure is now in process, according to Wilson and Dr. John Collins, head of surgery, who expects the review will be completed this summer.

University records show Lucas was the principal investigator on two NIH projects in 1979. One ended last year, while the other is scheduled to expire at the end of 1981.

The first was a contract with the National Cancer Institute for direct assay of lymphokine. Initiated for one year in September, 1978, it was extended for a second 12-month period, expiring in September 1980. Total direct costs were $287,734.

The second was a three-year grant on factors negating response to mammary adenocarcinomas, starting in January 1979 and scheduled to end this year. Total direct and indirect costs for this grant amount to $219,256.

-more-

Collins became the principal investigator on these projects during the 12 weeks Lucas was suspended. As head of the department, Collins also has certified the accuracy of scientific and technical information contained in each grant application, contract proposal, and progress report submitted to NIH by Lucas after his reinstatement in 1979.

In his petition for rehearing on the issue of discovery concerning Lucas and Stanford, Dong cites an internal NIH file memo dated May 27, 1977, and a *Stanford Daily* article published June 28, 1977, as evidence of the University's misleading the public about the Feigen committee findings.

The NIH memo, based on a phone conversation with Carl Hitchner of the Stanford Legal Office, said that Hitchner had verbally "reviewed the actions taken at Stanford which resulted in a committee report that concluded, in general, that Dr. Lucas was not guilty of any fabrications or fallacious research reporting but perhaps guilty of sloppy laboratory administration.

"He mentioned that the committee report initially had come up with some unanswered questions and (that) a later submission by Dr. Lucas answered most of these questions to the committee's satisfaction but still left the question of sloppy laboratory administration."

The *Daily* quoted University Legal Counsel John Schwartz as saying "neither (the 1973 or 1975) committee found any evidence of any deliberate scientific misrepresentation."

In a Jan. 29, 1979 letter to NIH, Schwartz said Hitchner recalled "a great effort on his part to be precise (in talking with NIH) with regard to just what the committee did and did not find. . . .

"Informal telephone conversations are not a particularly satisfactory means of communication when it involves drawing and appreciating the difference between a conclusion that something did not exist and a conclusion that there was not enough evidence to conclude that something did exist." Shortly thereafter, NIH was informed of Lyman's public sanctions against Lucas.

A brief submitted for the University to the California first district court of appeals by the University says: "The Feigen report concluded that 'the question of fabrication and fraud is unresolved.' The remarks attributed to the University in hearsay memoranda (from NIH) and newspaper clippings cited by Dr. Dong say essentially the same thing."

In a separate legal case, settled out of court in January, 1981, Dr. A. Baronio Martins, a former research associate of Lucas, charged Lucas had libeled him in grant applications to NIH and that Stanford had denied Martins had a three-year contract even though this was stated in the grant application.

In a deposition for the Martins suit, Kenneth D. Parker, criminologist and toxicologist, claimed some research by Lucas was "science fiction."

Parker said analysis of the inks used in Lucas' research notebooks suggested some entries had been fabricated or altered. In addition, five rats in one control group of Lucas' experiments "never existed," Parker claimed.

In material disclosed by the University in response to a court order, the Feigen report noted that "We purposely have not studied in depth the large amount of materials presented by Dr. Martins, feeling this dispute will be aired elsewhere and that the charges did not lend themselves to an appropriate examination by our committee."

STANFORD—

Daily room rates at Stanford University Hospital will go up an average of 12.2 percent, starting September 1.

The rate increase is included in the Hospital's proposed $146.6 million budget for fiscal 1981-82, which is being submitted for approval by the Board of Hospital Directors to the general members of the Hospital Corporation, the Stanford University Trustees.

The budget figure includes $7.1 million for needed equipment and capital improvements during the coming year.

Dr. Lawrence G. Crowley, president of the Hospital, said the increases are necessary because of higher wages and benefits for employees, increased care requirements of patients being admitted, inflation and higher costs for supplies and equipment, and significant reductions in reimbursement from the government programs of Medicare and Medi-Cal.

Hospitals in general are facing decreasing federal reimbursement as a result of payment limitations imposed by the new federal budget. Payments for some kinds of care given to Medicare and Medi-Cal patients increased only three to six percent over the current year. At Stanford Medicare and Medi-Cal patients account for about 49 percent of the Hospital's patient days.

The daily cost for medical, surgical, and gynecology services will be $257 for ward accommodations, $274 for a semi-private room, and $318 for a private room.

Medical, surgical, and gynecology patients utilizing services of resident physicians will pay $19 more per day than the above rates. The patient's attending physician determines whether such services are utilized.

Crowley noted that measured in terms of nursing hours per patient day, Stanford attracts an increasing number of patients with the most critical and complicated diseases.

"On the average they require both greater nursing skills and hours of care than patients admitted to nonteaching hospitals," he said.

Nursing hours per patient day are running about six percent higher than anticipated on routine care units. Normally such high intensity of care is found only in coronary and intensive care units.

However, for these routine cases the length of stay at Stanford is 11 percent shorter than most hospitals with 400 or more beds. The shorter stay is attributed to the results of intensive nursing services and higher mix of registered nurses.

Rates for some specialized units such as intensive care will go up 11 percent, obstetrics 10.9 percent and basic nursery 9.6 percent.

The Hospital increased its room rates an average of 10 percent in July to compensate for unexpected costs in the current year. At the time officials announced that further increases would be necessary for fiscal 1981-82.

Patient revenues make up 99 percent of the Hospital's funds. The Hospital has no tax support as do district hospitals or government-supported hospitals.

STANFORD—

The first Charles E. Culpeper Visiting Professor at Stanford University School of Medicine is Dr. Dean Warren of Emory University in Atlanta, a world renowned expert on the liver and biliary tract, the Dean's Office has announced.

Dr. Warren, the Whitehead Professor and chairman of the department of surgery at Emory University, will visit Stanford Medical School on August 28 and 29 as a visiting professor in the Department of Surgery.

Warren will deliver a talk on "Portal Hypertension" at the Department of Surgery grand rounds at 8 a.m. on August 29 in room M112 at the Medical School.

Warren, who received his M.D. degree in 1950 from Johns Hopkins School of Medicine, was dean of the school of medicine and vice president for medical affairs at the University of Miami prior to joining the faculty at Emory University.

This is the first year of a five-year rotating Culpeper Visiting Professorship at Stanford Medical School. Next year, the Professorship will be in the Department of Medicine, according to the Dean's Office.

The Charles E. Culpeper Foundation of New York supports primarily health, education, science and technology programs. The Foundation also offers grants to support arts and letters, youth activities, administration of justice, and native American affairs.

STANFORD—

A new policy governing the access of community physicians to Stanford University Hospital's specialized services and laboratories was approved Wednesday, August 12, by the Board of Hospital Directors.

Drafted by a committee of the Board, headed by Mrs. Linda Meier, the new policy is consistent with the recommendations of the Palo Alto Community Physicians-Stanford Medical School Liaison Committee announced in June.

After laboring for more than two years, the Liaison Committee had reached agreement on the principle of community physicians having controlled access to certain Hospital-based clinical services and laboratories and on the rules for replacing those community doctors who leave.

Under previous Board policy future access to such services was limited to Medical School faculty responsible for clinical academic programs.

The new Board policy provides for the granting of clinical privileges to the Hospital-based services and laboratories to the following medical staff members:

- full-time and part-time paid faculty of the Stanford University School of Medicine;
- community physicians who were members of the medical staff as of August 1, 1978, and who held clinical privileges in those services;
- community physicians on the voluntary clinical faculty who qualify as replacement physicians under the new guidelines;
- community physicians who qualify as courtesy physicians under the Palo Alto City-Stanford contract, which guarantees access of community doctors to Hospital beds;
- community physicians who affiliate with the School of Medicine to teach and do research under full-time faculty supervision.

The Board said:

"The adoption of these recommendations is consistent with the need to maintain excellence in patient care in the Hospital, the need to maintain strong teaching and clinical research programs within the Hospital-based services and laboratories, and the need to fulfill the Hospital's responsibility to the community."

The Board also adopted a resolution, appointing a committee to consider further community involvement in new Hospital-based services and laboratories that might become available in the future, as well as issues related to access and utilization of Hospital-based and admitting services.

The committee will be composed of three Board members, three community physicians, and three faculty physicians. The committee will also guide the board on the impact of new appointments on patient care, operating costs, the teaching and research missions of the Hospital, and its responsibility to the community.

STANFORD—

Volunteers are needed to participate in a nutritional research project being conducted by Dr. Gerald Reaven and associates at the Clinical Research Center of Stanford University Hospital. The study is designed to investigate metabolic effects of two levels of dietary carbohydrate.

Recent recommendations of the American Diabetes Association and the American Heart Association suggest certain benefits from a low fat, high carbohydrate diet. But researchers at Stanford aren't sure.

"We feel," says Reaven, "there is enough information to suggest that those recommendations, taken without consideration of individuals' metabolisms, could be potentially harmful for certain people."

He also states that the *form* of the carbohydrate intake must be taken into account: for example, string beans are quite different from coffee cake.

In their study, researchers here will attempt to see what happens with two separate diets which vary as to proportions of fat and carbohydrate. In the past, says Reaven, such experiments conducted with formulas proved negative results for increased carbohydrate. Now he's interested in trying the study with real foods.

The subjects being sought—both male and female—should be 21 to 65 years old, and *not* currently in any medical or dietary therapy for diabetes or hyperlipidemia. They *should,* however, have a history of boarderline or mild diabetes; a family history of diabetes or coronary heart disease; a history of abnormality of blood lipids (cholesterol or triglyceride); or a family history of abnormality of blood lipids.

Accepted volunteers will be provided with free meals for 30 days, as well as a medical examination and dietary evaluation, a routine chest X ray, cardiogram, liver and kidney function tests, and evaluation of blood sugar and lipids. The project will not interfere with subjects' routine daily work schedules.

Those interested should call Ann Coulston, R.D., at 497-5430, from 9 a.m. to noon; or George Liu, M.D., at 497-6054, from 1 to 6 p.m.

STANFORD—

Dr. Inder Perkash, associate professor of surgery, has received the 1981 Speedy Award from the Paralyzed Veterans of America.

The award is made to the person of all countries for the most outstanding contribution in the field of spinal cord injury.

Perkash was honored by PVA'S "highest form of acknowledgement" for his contributions to SCI medicine in the field of urology. In addition he was recognized for founding and directing the Spinal Cord Injury (SCI) Center at the Palo Alto Veterans Medical Center and his research there in urodynamics.

Perkash is also considered a leading international authority on surgical procedures and management of neurogenic bladder dysfunction.

Last October he became the first faculty member of a medical school to be appointed to the PVA Professorship of Spinal Cord Injury Medicine Chair.

Perkash received his award at the PVA Annual Convention Banquet in Denver July 24.

STANFORD—

Dr. Stanley N. Cohen, professor and chairman of Stanford's department of genetics, is the recipient of the Marvin J. Johnson award of the American Chemical Society (ACS).

The award recognizes Cohen's contributions to the advancement of microbial and biochemical technology, particularly in the development of recombinant DNA research.

Cohen's test-tube construction of biologically functional recombinant DNA molecules has been considered a milestone in genetic research.

His work in 1972 and 1973 sparked the recent rapid developments of genetic engineering including the production of such biologically active hormones as insulin, somatostatin, and the anti-viral drug interferon by bacterial "factories."

Cohen will deliver his award lecture entitled "Cloning and Expression of Genes in Heterospecific Hosts" on Aug. 26 in New York City at the ACS Microbial and Biochemical Technology Division's annual convention.

STANFORD—

"I suspect there are minor risks from spraying (of malathion), but they're from helicopters' crashing into houses and from people's falling off ladders while stripping their apricot tree," concluded notable Berkeley biochemist Bruce Ames at a recent Department of Medicine's grand rounds.

Ames, *San Francisco Chronicle* science writer David Perlman, Stanford President Donald Kennedy and Department of Medicine chairman Kenneth Melmon comprised the panel of a rather unusual Thursday grand rounds, "The Community as Patient."

From his own singular perspective, each member dissected the data and the events that were seemingly leading the area's population to near panic.

The consensus seemed to be now that the confusion had started to settle that the original fears were mostly unfounded—the doses being dropped were too small and malathion seemed to be relatively harmless.

"I think part of the problem is that all risks are competing risks," said Ames, who has been a leader in developing sensitive tests for environmental carcinogens and mutagens.

"It is one thing to look at malathion all by itself and say, oh yes, the result of this test or that test is... But, in a way, that's not fair because nothing is risk free and the alternatives have risks.

"You always must think how it fits into a larger picture. If everyone leaves Palo Alto, then there is a risk that with a million people driving an average of 60 miles one of them will crash into a tree. Plus there is the consideration of all the carcinogenic automobile exhaust that's being put up into the air.

"Plus, if the medfly isn't stopped now, tomorrow worse pesticides will have to be used. Part of the problem in decision making is that people don't tend to say what the risks are if we don't do it.

"I really started thinking about this when I almost fell off my roof while I was cleaning my gutter. I started thinking about all those people climbing up on their roofs cleaning their solar collectors and the roofers installing the solar collectors. I looked up the statistics on roofers, and in fact, roofers fall off roofs fairly frequently. Yet everyone claims solar energy is absolutely safe."

Ames said that malathion is the safest organophosphate pesticide, and organophosphates are the safest kind of pesticide because they break down relatively rapidly in the environment. In addition, Ames said malathion is such a weak pesticide that it was almost abandoned in the early stages of development because the manufacturers thought it would prove almost useless.

It is the garden-variety pesticide, one that people use to spray their roses, one used to rid English school children of head lice. In fact, he said that if you spray your roses as directed on the bottle of malathion it is possible to buy at your local garden store, you'll get quite a bit higher dose than from the bait applications.

-more-

 English school children are also dusted with much higher concentrations than is being sprayed, and although no thorough epidemiology study has been done, the studies that have been done reveal no serious side effects, he said.

The concerns about malathion centered on its possible long-term effects.

Ames recounted the various tests for carcinogenicity (ability to cause cancer), mutagenicity (ability to cause mutations) and teratogenicity (ability to cause birth defects)—the standard concerns about any chemical.

"It has a pretty clean bill of health as far as carcinogenicity tests go," he said.

Malathion was tested in enormous doses—much higher than most chemicals are scrutinized—in rats and mice, up to a few grams a day. Out of six separate tests, in only one strain of male mice at one dose was there a statistically significant increase in one kind of liver tumor. In reviewing the results, the National Cancer Institiute decided that this evidence was too tenuous to be damning, given the variability in controls, he said.

Ames did add the qualifier that rats and mice are imperfect models for people, and it can never be said for sure that if a chemical is noncarcinogenic in rats and mice, it's also noncancer-causing in people.

But he continued:

"Even if it were a carcinogen, there is probably little danger because the amount being dropped is so low."

The most relevant tests—those in rats—of malathion's ability to cause birth defects turned up no incriminating evidence, he said. One test that involved injecting malathion into a chick embryo resulted in some abnormalities, but it's not clear what that test means, he said.

Eight different tests done in bacteria and yeast probing for any ability of malathion to produce mutations in the genetic material proved negative, he said. Two other tests turned up barely positive.

"Overall, the toxicology has been negative, just those two little clouds," he said.

Ames said that no really convincing studies have been done on humans, even though it has been sprayed on a number of population centers. Some of the reason stems from the difficulty of designing defensible tests, he said.

"People exaggerate the power of epidemiology," he said. "The big thing is something called confounding variables."

People are exposed to so many different things, it's near impossible to pin the blame on a particular agent, he explained.

"Given the incredibly low doses of malathion being dropped, it's not justifiable that the definitive study to pick up something on malathion can be done in Santa Clara county," he said.

Science writer David Perlman, who attempted to provide the public with daily updates on malathion, said he was confronted with daily deadlines and gaps in the flood of information coming from various sources and an even more chronic problem:

"One problem the media copes with all the time, that the public has never been able to thrash out for itself, is the idea that somehow when you use the word risk you are saying danger," he said. "The public takes the word risk far beyond what is appropriate."

-more-

Melmon said he first became aware of the seeming magnitude of the problem when he received a phone call for help from the California Highway Patrol on the Saturday night before spraying was due to begin. The Patrol feared that at a minimum 25 per cent of the population might flee the Santa Clara Valley because of the high anxiety over the possible toxic effects of the insecticide.

State and local governments soon asked for a measured, official response from Stanford about the risks, Melmon said.

Institutions like Stanford can't become experts and pronouncers on everything, and probably shouldn't, said Kennedy.

The real question becomes how do you know when it is terribly important to have a consensus view to present on behalf of the institution, as opposed to a set of more limited views on behalf of interested individuals, he said.

Perlman said it probably would be difficult to develop a consensus in such a fast-moving controversy as that over the Medfly because of the various strongly-worded faculty opinions.

He suggested that what probably should be aimed for is a rapid mobilization of the spectrum of opinion that exits, and then its presentation to the public through the intermediary of the press. He also proposed that the University line up people who could explain the relevant, sometimes cloudy data to the press.

Kennedy considered how physicians should respond when the inevitable questions from their patients come.

"No one is in the position to offer absolute assurances about malathion or about other chemicals. We must remember that there are not any real absolutes in this business," he said.

"And it is very near the heart of medical practice to be prudent in the face of uncertainty, even rather distant uncertainty. Yet, even in a public health situation like this one, the things that doctors tell their patients or the things that scientists caution are distant possibilities become frighteningly close.

"The obstetricians that recommend to pregnant women that they leave are doing at one level something very prudent, yet when that advice becomes widely reported it becomes a source of concern that can grow out of all proportions to the hazard."

Everyone seemed to agree on one thing. The Medfly had caught most people unawares.

"It seems to me there has been a lack of political leadership," said Ames, "On many of these questions, much depends on how serious the Medfly is. No substance is absolutely free, so how important is it to spray?

"I thought that it came out relatively late in the newspapers that Hawaii has had a lot of trouble, that the Medfly isn't some ordinary insect."

Melmon concluded that "what we have to do in the future is have more of an early response system in place for issues that we may inevitably have to answer as an institution."

EDITORS: Details follow asterisks.

STANFORD—

The first encouraging results from clinical studies involving the use of monoclonal antibodies in the treatment of cancer patients have been reported by researchers at Stanford University School of Medicine.

The studies are still preliminary and limited to a few patients whose cancers were only temporarily or partially controlled. Nevertheless, the results have added cautious optimism to the field of applying immunologic methods to the treatment of cancer, the researchers said.

Two patients, one suffering from leukemia, cancerous proliferation of the white blood cells, and the other with lymphoma, cancer of the lymphatic system, were administered monoclonal antibodies produced in the test tube by mouse hybridoma cells.

The patients, both of whom had advanced disease and had failed to improve with conventional cancer treatments, drug therapy and radiation therapy, each showed some evidence of benefit from the antibody therapy, according to Dr. Richard Miller, Dr. Ronald Levy and their colleagues at Stanford.

This is the first time that clinical benefit from monoclonal antibodies has been documented. Lev said.

Reports on each patient's therapy have been published in the August 1 issue of *Lancet* and the July issue of *Blood*.

Levy is associate professor of medicine (oncology) at Stanford and Miller is a research associate in oncology. Their co-authors on the *Blood* article are Dr. James McKillop and David Maloney.

Following those promising trials, four more patients have been treated at Stanford with mouse monoclonal antibodies, with encouraging results, said Levy.

One important aspect of the recent studies, Levy stressed, was to establish whether or not it is safe to give mouse antibodies to humans. Since the mouse antibody is a foreign protein, researchers did not know if the patient's own immune system would tolerate the substance or whether it would give rise to serious allergic reactions.

However, in the published results, one patient showed no anti-mouse immune response, and the other had an insignificant response that disappeared within a few days. All six patients receiving therapy thus far tolerated the mouse antibody without difficulty, Levy said.

This finding opens the way for further development of mouse monoclonal antibodies as a new mode of cancer treatment which can be combined with traditional methods such as radiotherapy and chemotherapy, he pointed out.

The production of pure monoclonal antibodies is based on the 1975 discovery by George Kohler and Cesar Milstein in Cambridge, England, that mouse tumor cells can be fused with antibody-producing cells of the immune system, called lymphocytes, to create a new cell called a hybridoma.

Hybridomas inherit the quality of immortality from the cancer cell progenitor, and the ability to produce a specific antibody from the lymphocyte.

Methods are available to identify and select out from millions of hybridoma cells, the one that secretes the desired antibody. Its ability to continually multiply in the test tube allows researchers then to cultivate large quantitites of pure and specific antibody.

In three of the six patients, the antibody treatment produced significant improvement, particularly evident in those who had a form of lymphoma involving the skin, called mycosis fungoides. In one 67-year old male patient, healing and shrinkage of skin tumors was observed and some of his skin lesions completely cleared during the course of antibody therapy. Levy and Miller reported in the *Lancet* article.

However, monoclonal antibody therapy has not succeeded in completely curing any patients' cancer, Levy cautioned.

"For the present, antibody therapy is no substitute for more traditional and proven methods of cancer treatment such as radiotherapy and chemotherapy," he said. "However, we hope that antibodies will prove an additional modality of treatment that can be combined with current methods."

In the meantime, "a great deal more development and testing is required before antibody therapy may be generally available," Levy added. "The current results are encouraging enough to make further investigation worth while."

Levy's work is supported by the Howard Hughes Medical Institute and by grants from the National Institutes of Health and the American Cancer Society.

. . .

Antibodies are proteins produced by cells of the immune system called lymphocytes, in response to the perception by the body of foreign substances such as bacteria and viruses. Each lymphocyte produces just one highly specific type of antibody.

There are millions of different lymphocyte types that enable the body to contend continuously with the variety and heterogeneity of foreign agents it contacts. Antibodies help the body combat foreign agents by recognizing and binding specifically to the particular substances that identify the agents. These substances are called antigens. Other "effector" cells-from the immune system then eliminate the antibody-bound substances from the body.

In the case of monoclonal antibody therapy for leukemia and lymphoma. Levy and his colleagues use an antibody that recognizes antigen molecules which sit on the surface of normal lymphocytes but are found in much larger numbers on the surface of cancerous lymphocytes.

Once the antibody is administered. it attaches to the target cells and the body's own defenses remove and destroy the cancer cells.

Previously, researchers had presumed that only human monoclonal antibodies would prove tolerable for therapeutic purposes. However, because human cells are much harder to work with in the laboratory, it might be several years before useful human monoclonal antibodies are available for testing, Levy said.

Why the foreign mouse antibodies failed to trigger an immune response in humans is not certain, according to Levy. As the most likely explanation, he suggests that because the patients had already received drug treatment known to suppress the immune system, their tolerance of mouse antibodies might be a sign of overall immune system sluggishness. This hypothesis is being explored now in experiments with monkeys, Levy said.

3-3-3 Two problems with antibody therapy Levy and his colleagues recognized in treating their first patient; one concerns antigen molecules floating free in the blood that can bind to the administered antibody, in effect "sopping it up" before it can reach the antigens on the tumor cells.

The other problem, called antigenic modulation, involves the temporary disappearance of antigen from the tumor cell surfaces during a two to three day period following an antibody dose. Either the antigen-antibody complexes may fall off the tumor cells or they may be engulfed inside them, suggested Levy. In either case, the tumor cells lose the antibody signals that alert other cells in the immune system to destroy them.

However, since the antigens begin to reappear on the cancer cell surfaces several days after an antibody treatment, by carefully linking the antibody dosage schedule to the rhythm of antigen production in the tumor cells, this problem can be controlled, Levy said. (For instance, in one patient, antigen on the tumor cells diminished for three days following an antibody dose, reappearing on day number three or four. His antibody dosage schedule was therefore set at one dose every four days.)

Careful timing of antibody administration also minimizes the sopping up effect of free antigens circulating in the blood. The free antigen molecules seem to be shed into the bloodstream as tumor cells are destroyed, releasing them from the surface. Since the body clears the circulating antigens within about 24 hours, however, doses can be scheduled when free antigen is at a minimum. (The level of free antigen can be measured by a test known as a radioimmunoassay.)

Due to the sophisticated immunologic techniques required to prepare pure monoclonal antibodies and to monitor antigen modulation and free antigen levels, Levy emphasized that this type of work can only be performed at present in institutions with special expertise in immunology.

The patient described in the *Lancet* article had a "dramatic response but at no time was he free of all detectable disease," the doctors reported, describing his condition as "a stable, partial remission."

The patient's skin and peripheral blood disease remained stable and in remission after 10 weeks of antibody therapy, but the treatment was discontinued when the cancer started to grow back in lymph nodes. Further radiation therapy was not successful and the patient died four months after the initiation of antibody therapy from cancer in the lymph nodes, but "with skin and peripheral blood disease still in a partial remission," the doctors noted.

Monoclonal antibodies may also be useful in monitoring the course of disease during therapy or to detect recurrent cancers early, Levy said. "They can help physicians detect low levels of leukemia cell products in patients' blood or detect small numbers of leukemia cells themselves," he added.

Theoretically, it might be possible one day to precisely custom design antibodies for therapy and monitoring of each individual patient, Levy speculated.

Another possibility would be to hitch toxic chemicals to the antibodies which would then zero in on the cancer cells, targeting the chemical's destructive powers directly on the tumor, explained Levy, but so far he and his colleagues have only tested direct administration of antibody alone.

And, although Levy and his colleagues now are testing monoclonal antibodies only in certain leukemia and lymphoma patients, other investigators are using monoclonal antibodies effectively against some solid tumors in animals. Within a few years, such investigations could commence in humans, the researchers predicted.

In addition, monoclonal antibody therapy may prove useful in combatting other diseases caused by bacteria, viruses or parasites, and in therapy for some autoimmune diseases.

STANFORD—

Karen Wilson of Mill Valley, Calif., died Saturday (August 1) at Stanford University Hospital. Wilson, who was 28, had received a heart-lung transplant on Tuesday (July 28.)

She died at 8:30 a.m. as a result of kidney and liver failure that resulted from complications encountered in the transplant surgery.

She is survived by her mother, Mrs. Betty Brashear, stepfather, Mr. Turner Brashear, sister, Mrs. Donna Cameron, and her father, Sid Wilson of Henderson, N.C.

Ms. Wilson had been born with a congenital heart disease. Last January she had a cardiac arrest and her condition worsened considerably, and it was thought she had only a few months to live.

"I've never had any second thoughts," she said talking about the operation in a recent interview. "This is my only chance. I want the operation because I want to lead a normal life. I've lots of determination."

This was the third heart and lung transplant at Stanford. Mary Gohlke, 45, a Mesa, Ariz., newspaper advertising executive, received the first heart-lung transplant on March 9. Charles Walker, 30, of Binghamton, New York, received the second on May 1.

Both Gohlke and Walker are still recovering from their operations. Gohlke has had to be briefly rehospitalized three times for minor complications since her initial June 1 release. Walker has been free of complications.

Both are still living in the Stanford area for the time being, but may be able to return to their homes sometime this autumn if no complications develop.

STANFORD—

A special program entitled "Depression: behavior and the brain" will be presented Thursday, Oct. 22, at 8 p.m, in the Sherman Fairchild Auditorium of Stanford University School of Medicine.

Sponsored by the Friends of Psychiatry and Behavioral Sciences at the Medical Center, the program will feature as speaker Dr. Philip A. Berger. The moderator will be Dr. Thomas A. Gonda, professor and chairman of the Department of Psychiatry and Behavioral Sciences.

Berger is presently associate professor of psychiatry and behavioral sciences. He also serves as director of the Stanford Mental Health Clinical Research Center, and director of the Schizophrenia Biologic Research Center. He first came to Stanford as a resident in psychiatry in 1970, and was an assistant professor from 1974 until 1980.

The lecture on depression is open to the public, admission is free of charge, and there are no reserved seats. However, in order to plan for adequate seating, the organizers would appreciate being notified of any individuals' or parties' intention to attend.

The Friends of Psychiatry and Behavioral Sciences is a public information and fund raising organization associated with the Medical School. It is located at 800 Welch Road, room 201.

For further information regarding the upcoming program, as well as other activities of the organization, call 497-6376.

FOR INFORMATION CONTACT: Mike Goodkind (415) 497-6911

(EDITORS: This profile marks the stepping down from active clinical duties of Allen Barbour, professor of clinical medicine. His views on patient care represent four decades of medical concern in private as well as university practice).

STANFORD—

Dr. Allen Barbour's chart notes were different.

When he was a chief resident nearly three decades ago, a philosophy of medicine was already being reflected in his medical chart notations.

For Allen Barbour's chart notes weren't the typical one- or two-sentence scribblings.

Some patient entries, recalls an intern who served under Barbour back in 1952, would run five and six pages, intimately detailing a patient's life situation.

"You could argue that I'm full of baloney or that I'm too wordy," Barbour laughs. "Or you could argue," he adds more seriously, "that I'm trying to look at all aspects of an illness that another person might ignore."

Looking for illness—the total component of a patient's suffering—rather than just an isolated disease, has been Barbour's commitment since his student days.

Now he's 63 and has sought emeritus status as a professor of clinical medicine to write a book, **Human Dimensions in Medicine**, which he feels will synthesize his views about the human side of medicine. He also is serving as associate university ombudsman for the Medical Center.

But he continues to spread the gospel—although he wouldn't call it that—and gently or sometimes aggressively chide colleagues whom he believes can focus so closely on disease symptoms that they lose sight of the patient as a person.

Many of his Stanford Medical School colleagues and former students were to hear Barbour once again emphasize his views Oct. 29, when he holds Medical Grand Rounds.

Later his colleagues will honor him at an evening banquet. Announced will be an endowment providing an annual Allen Barbour award to the medical student who reflects those personal and scholarly traits of the prize's namesake.

An award perhaps is fitting for Barbour, who has won countless teaching honors from his students each year at Medical School graduation.

His instructional duties at Grand Rounds will reflect his philosophy and will also focus closely on a topic of practical significance. The title is *Psychogenic Chest Pain.*

"The cause of about 60 percent of all chest pains cannot be traced to a specific source or disease. While some of these may be caused by various physical strains, the vast majority appear to result from emotional components.

"If doctors don't consider those emotional components, they're not likely to get good results.

"The positive approach involves understanding the patient as a person. Then perhaps we might help the patient trace the cause of his chest pain to its emotional sources.

"I'd like for doctors to be able to say that a chest pain results from a certain human anguish, rather than simply saying that no known cause or disease is present."

-more-

Barbour's medical history began at the University of California at San Francisco where he received his M.D. in 1943. It was during World War II then, and Barbour served in the Navy, including an internship at the U.S. Navy Hospital at Oakland.

After postgraduate training at Massachusetts General Hospital and in England, Barbour became chief resident at the University of California Hospital in San Francisco for a year in 1952.

Then Barbour went into private practice for the next 10 years.

"I enjoyed private practice; my brother was my partner. We got along very well.

"I can't say that I left it from any dissatisfaction. The only dissatisfaction was that I got to working too hard. I didn't know how to reduce my practice, or I wasn't able to I guess. I'd say yes to everybody."

During that decade, Barbour served as a voluntary faculty member at the University of California, and finally:

"It occurred to me that I was a scholar at heart. A closet scholar.

"I'm not exactly a publishing researcher by any means, but I like the scholarly environment, so I looked into a university appointment where I could blend my ideas about clinical medicine with the teaching of students and residents.

"And Stanford was interested, so here I am—a Cal man at Stanford.

"Besides," Barbour continued, "private practice is a little on the lonely side. You're making your own decisions. There's nobody to talk problems over with. You can't have dialogue regularly.

"And then you miss the kind of academic discussion, grand rounds, specialty conferences.

"It's quite different. The main source of scholarly input as a private practitioner is your own reading and consultations with other doctors, so you glean their specialty knowledge in the act of taking care of a patient. But it's easier in an academic environment."

And that's where Barbour has spent the last 18 years—teaching, seeing patients in clinics, and serving as a scholar vitally interested in the course of medical education.

How would Barbour, since 1974 a professor of clinical medicine, change the course of medical education?

"I think I would start by teaching students analysis of symptoms that would be straightforward and practical.

"You see, textbooks aren't organized by symptoms and illnesses. They're organized by diseases. So if you read a textbook on internal medicine, you may note in a chapter on hypothyrodism that fatigue is a symptom of that ailment.

"And then you read a chapter on disease of the adrenal cortex and find that people with Addison's disease have fatigue.

"But nowhere in the book does it tell you that 80 percent of all patients with fatigue have no disease at all. That's not known to most physicians.

"So they spend endless time and money on tests to wind up only with a diagnosis of fatigue of unknown etiology, which of course is an illness and not a disease.

"Medical students need to understand diseases, because that is important. I'm not in any way putting down the disease model in medicine. I'm just saying it needs to be fitted into a more comprehensive model."

The interest in the human side of medicine evolved naturally for Barbour, he believes.

"Once you get intrested in the human side of medicine, the technological side gets more and more uninteresting.

"For example, the first time you see a lobar pneumonia, it's very interesting. As a student, you've read about it, and now here's a real disease and real chance to help someone.

"But by the time you've made the same diagnosis a hundred times, you're pretty familiar with the diagnosis, how to treat it and all its complications.

"It ceases to be interesting.

"But the people that have the pneumonia are always interesting.

"I mean medicine is a marvelous way of having contact with a lot of people from all walks of life. There's hardly anything else which gives you that opportunity. You not only have contact, but intimate contact. You're engaged in their inner secrets and problems.

"So that no matter how uninteresting the common cold is, it's the person who has it that's interesting. So medicine becomes interesting."

Time pressure is a widely known feature of a physician's life, and Barbour concedes that doctors have to use their time judiciously. That's one reason, he feels, that support personnel and health educators should take over some of the functions modern doctors have been called on to perform.

"If a doctor spent two hours a day teaching all his patients how to eat better and exercise better, he would have to see six fewer patients who were sick and needed help.

". . . I think that a lot of work that doctors do should be taken over by other people. Obesity for example is not a good place for a doctor. He doesn't have that much time and energy to formulate diets and monitor patient's daily diet habits.

"I think Weight Watchers and places like that do a better job. They see the patient weekly, they charge less, and there is a combined group approach which can be supportive and helpful.

But on the other hand, Barbour believes that even when doctors can spend only a few minutes, that time can be marshaled to serving patient needs.

"It's very hard to learn about a patient or be supportive if you only have 10 minutes. But sometimes that really is all you have. Therefore, you've got to learn how to make that time count.

". . . I think there is a lot of time wasted on things which are not the most important. We go through a lot of motions. Even though there is no chest disease, we may sit the patient up every day, tap the chest, listen for rales, 'play doctor.'

"Well, you can generally tell whether you need to do that or not. If the vital signs are all normal on the nurse's notes, and there are no complaints, your time might be better spent talking to the patient aboiut his or her life situation.

"Take the case of a patient dying of cancer. You've got 10 minutes. You might spend a lot of time on biomedical details which are no longer significant.

"What the patient really needs at that point is for someone to spend the 10 minutes in a more intimate interpersonal relationship of doctor and patient as people."

Another example, cites Barbour, might be a patient with cirrhosis of the liver. Physicians hover over his bed debating endlessly which diuretic to use.

"But the basic problem is alcoholism, and no one is talking with the patient about the human situation which causes him to drink and what might be done about that.

"The patient will get out of the hospital and he'll be back two months later because he'll hit the first bar when he leaves."

Specialization, Barbour believes, is no excuse to avoid the human side of medicine.

-more-

"I think that the development of psychiatry in the 19th century was a real detriment to medicine, because it separated in practice the psychosocial aspects of illness from the physical aspects of medicine. That, unfortunately, relieved the 'real' doctors—non-psychiatrists—to deal with the body, because the psychiatrist ought to be dealing with the other things."

Specialties, he says, need to draw from each other, but all must become involved in human care.

"The system is conducive to making technologists out of physicians. Those physicians who perform technological tasks may be particularly vulnerable to this problem.

"But there are notable exceptions. Take (Dr. Norman) Shumway (chief of the cardiovascular surgery program).

"He likes people. He's got a good sense of humor.

"He may only spend a minute or two with the patient, but there's some real contact there on his daily rounds.

"We need people like that who are superb surgeons, but that doesn't mean they can't be friendly at the bedside."

Of course during the past few years, much of Barbour's activities have involved working with medical students. Have they changed?

"There isn't much difference over the years, with the exception of the Vietnam War. Those students were different.

"The war was such a turbulent time that I have to say that there were a number of students in medical school who were there primarily for the purpose of getting out of the draft.

"Now they were smart. And it doesn't mean that they didn't become good doctors. But that wasn't their primary motivation.

"... Now the students are pretty much as they were before the war."

Of course individual students are different within each class regardless of era. Some students have an instinctive feel for the human dimension of medicine, Barbour believes, while some do not.

"This is a tricky thing. I don't understand what makes people care about patients. It has no connection with anything.

"Researchers sometimes are the best doctors at the bedside. Some people who say they are going into psychiatry or going into country practice may or may not really care about patients.

"On the other hand, some students who may want in part to get into medicine to make a lot of money, may become very fine physicians, very concerned about patients.

"Caring about patients is a very peculiar quality. I can't predict it ahead of time, but after 40 years of practicing medicine, I can tell within one or two times with a student at the bedside how he or she will become.

"It's the way they listen, the way they talk, and the way they accept the patient for where or what he is."

STANFORD—

A patient waiting area intended to free Stanford University Hospital beds earlier in the day opened Monday (Sept. 21) in the PATS lobby of the Main Center.

Staffed by nurse Joann A. Miyao and transporter Harden Stamps Jr., the waiting area is designed for recently discharged patients who are not able to leave the Hospital by the 10 a.m. checkout time, said Sandra Perkins, director of patient admitting services.

"The unit has been established to facilitate an earlier admission process and at the same time achieve regionalization of patients, a goal long hoped for in this hospital," said Perkins.

"The hope is that by providing a holding area for ambulatory discharged patients who are waiting transportation home or discharge medications, the rooms that they vacate can be cleaned and made available for incoming patients," Perkins added.

Expediting the release of patients before 10 so that the patient's bed may be reassigned the same day is a long-term goal of Hospital administration, Perkins said.

The discharge unit consists of about a dozen waiting room chairs, television, games and magazines for the waiting patients. Requirements for admission to the unit will be ambulatory patients more than 15 years old with no more than an estimated three hour wait for a ride or their medications, Perkins said.

Excluded will be isolation patients, persons requiring major treatment during the wait, behavior disorders and certain other patients at risk.

The unit will be in operation from 10 a.m. to 3 p.m. Monday through Friday. Lunch will be provided to patients waiting through the noon hour, Perkins said.

Miyao said short-term parking for patient pickup is available in the doctor's parking lot adjacent to the unit.

The discharge unit was a joint effort between Nursing and Patient Admitting Services.

"Until patients physically leave the hospital they are still our responsibility," noted Perkins, explaining the need for the supervised waiting area for discharged patients.

TWO STORIES: Lisa Ames (415) 497-6911

STANFORD—

Eighty-six first-year medical students from all over the country plan to join the School of Medicine's student body for the current academic year, 1981-82.

An orientation program for the new students, of whom 38 percent are women and 26 percent represent minorities, was coordinated by the Office of Student Affairs, involving the participation of many second-year students. Taking place throughout this week, it is intended to welcome and inform the newcomers.

The program has included faculty and staff presentations, student panels, non-academic advising, recreational activities, tours of the Medical Center, and welcoming remarks by Drs. Lawrence G. Crowley, Donald Kennedy, and John Steward.

The Medical Students Association sponsored a "free day," Thursday, with an optional beach trip for new students.

Registration days are Sept. 28 and 29, and autumn quarter classes begin Sept. 30.

STANFORD—

The School of Medicine's Faculty Senate held its annual election of officers for the Committee of Five, last Friday, Sept. 18.

Out of five nominees, Dr. Avram Goldstein was elected chairman for the third year in a row. Goldstein is a professor of pharmacology.

The other members elected to serve until Sept., 1982, were: Robert Cutler, professor of neurology and chairman of the Committee on Courses and Curriculum; Frances Conley, assistant professor of surgery; Lubert Stryer, professor of structural biology; and Robert Lehman, professor of biochemistry.

The Committee of Five is the ruling body of the Faculty Senate, which is a representative body of all the departments in the Medical School. The Committee sets agendas, appoints committee members, and makes the Senate's administrative decisions. Besides the chairman, it is to be composed of two faculty members from the basic sciences and two from the clinical sciences.

Participants are needed for a study examining the effect of aging on the sexual response of men and women. This research is being conducted in the laboratory of Dr. Julian Davidson, professor of physiology.

Menopausal women who have not menstruated for the preceding year or longer, and men over the age of 50 are sought. The study involves blood sampling for the determination of hormone levels and the use of noninvasive psychophysiological measures. Remuneration is available.

Anyone interested in learning more about this work is invited to contact Dr. Marie Kwan or Martha Morrell in the Department of Physiology, at 497-2434.

STANFORD—

Dr. David Glick, professor emeritus of pathology who was recalled to active duty in the Department of Radiology's Cancer Biology Research Laboratory, will receive a plaque and cash award Sept. 25, at the University of Minnesota, Minneapolis.

The honors coincide with Glick's presentation of the Gerald T. Evans Lecture, entitled "Development of Microanalytical Biochemistry—Some General Reflections," to be delivered that day. The lectureship is sponsored by the Department of Laboratory Medicine and Pathology at the University of Minnesota.

STANFORD—

In the event of a fire, an earthquake, or other emergency, many Stanford University Hospital personnel are now prepared to prevent injury to themselves and patients, thanks to a back care/patient evacuation training program (Back-Evac) initiated in 1978 and still going strong.

The objective of the program, organized by the Physical and Occupational Therapy Department, is to instruct all Hospital employees in back care, both on and off the job, and especially during situations which might involve patient evacuation.

The way both the basic and refresher courses work, says Joan Smithline-Zeiser, program coordinator and a physical therapist herself, is by instructing "trainers" from designated Hospital departments. The trainers are then responsible for providing training for all of the employees in their respective departments.

This season's courses, held in the last couple of months, were geared towards departments selected for participation because of their emphasis on patient orientation and care.

Next year, however, an effort will be made to involve every department throughout the Hospital, as the importance of the program has become exceedingly clear, says Smithline-Zeiser.

STANFORD—

The husband of an emergency patient shouts in anxiety at the unit clerk. A psychiatric patient, face contorted, wrings his hands and paces the floor. Hospital staff become agitated, sensing the potential for violent behavior.

To ensure calm and effective handling of situations like these by health professionals, the Facilities Protection Department was recently prompted to sponsor a workshop for 20 selected employees, on understanding, managing and controlling aggression in the health care setting. Participants in the program, held mid-September, were from NOB (inpatient psychiatric unit), Emergency Services, and the Facilities Protection Department staff.

The primary theme of the day was that specific verbal interventions—rather than aggressive reactions—are usually effective tools to help a person calm down and regain a sense of inner control. Said Allan G. Wickersty, Ph.D., the program leader, "When the aggressive patient or visitor is the *only* part of the scene that is out of control, then the crisis intervention team—led by security—has the best possible advantage."

Some of the verbal techniques he advocated for dealing with difficult situations include: deliberately ignoring inappropriate behavior, using humor to ease tension, explaining the rules, and expressing interest in the person's activities. Or sometimes, he said, just a firm "No!" does the trick.

Wickersty, a licensed psychologist and psychodramatist, first designed his training program in Washington, D.C., several years ago. Since then, he has conducted it with hospital Security and Emergency Department staffs across the country.

And he knows as well as anyone that talking isn't always enough to quiet an emotional explosion.

"For those crisis situations in which, by surprise or through escalation, an assault or violent behavior is already happening, or is unavoidable," he explained, "we teach skills in physical control techniques." However, he stressed, "Our goal and professional responsibility is to control aggression without injury of any kind."

Thus, the physical maneuvers taught in the course require body mechanics, leverage and control techniques that are non-offensive (not based on pain as the motivator)—and yet, powerfully effective. For example, simple techniques were demonstrated for dealing with hair and clothes pulls, bites, chokes, and wrist grips. Two and three-person restraints were also taught, requiring cooperation and teamwork, another skill emphasized in the workshop.

-more-

Wickersty sees the role of the hospital security officer as "the professional accountable for maintaining security by working with all the other professionals in a team effort that capitalizes on their pooled abilities." He teaches that teamwork extends to all hospital staff: clerks, housekeepers, nurses and physicians.

"We try to get away from relying on security as a last resort," he said. "If you leave the dirty work up to any one person, anger develops."

Wickersty used role-playing to demonstrate his theories. He had staff members play disturbed patients or visitors, while others acted out the roles of admissions clerk, nurses and physicians. This exercise, he said, makes staff more sensitive and helps them think of new peaceful ways to deal with irate or disturbed people.

Finally, Wickersty did not leave Stanford until the course participants proved they could use his verbal and physical techniques—on him. He role-played the part of a violent visitor, and it was up to them to calm him down, safely but surely.

"It's a very rare occasion that a situation like this actually arises," said Greg Homer of the Emergency Department, "but the information being presented here will be helpful in case it does."

Hilary Ryniewicz, director of Safety/Security Services, was quite pleased with the workshop. "The feedback was very favorable," he said. "We will try to continue to offer this program in the future, possibly involving other departments as well."

STANFORD—

Six tenured faculty appointments were approved Tuesday (Sept 15) by the Stanford University Board of Trustees.

Ferid Murad, who has been serving since July as chief of medicine at the Palo Alto Veterans Administration Medical Center, was named professor of medicine. He was recruited from the University of Virginia to Stanford, which operates patient care and teaching services at the VA Center.

Murad, 45, is renowned for his research into fundamental cell biology. His work has provided important clues to the origin of certain endocrine disorders and to the matabolism of tumors.

He serves on study sections of the National Institutes of Health, and as editor of the **Journal of Cyclic Nucleotide Research.**

A 1965 graduate of the Western Reserve University School of Medicine, Murad served as director of the Clinical Research Center at Virginia since 1971.

Also approved at the trustees September meeting were five Stanford University Medical School faculty members promoted effective Sept. 1 to the tenured rank of associate professor. These were F. Carl Grumet and Margaret E. Billingham, pathology; Frances K. Conley, surgery (neurosurgery); Bertil E. Glader, pediatrics; and Lawrence Meyer Simon, medicine (respiratory medicine).

Billingham, 51, a native of Tanga, Tanzania, has spearheaded developments in cardiac pathology, particularly in research involving Stanford's extensive cardiac transplant program.

She has provided a detailed system of measuring changes in the heart after transplantion which have helped doctors monitor patients.

Billingham came to Stanford as a pathology resident in 1966. She is a graduate of the Royal Free Hospital School of Medicine in London.

A Palo Alto native, Conley, 41, serves as chief of the neurosurgery section at the VA Center. She is a fellow of the American College of Surgeons and is pursuing important basic research in experimental tumor biology. She currently serves on the state Medical Quality Review Committee and is a graduate of Stanford Medical School.

-more-

Glader, 42, received his M.D. from Northwestern University. He was appointed to the faculty of the department of pediatrics in 1977 as co-director of the division of pediatric hematology. A 1980 he became chief of medicine at Children's Hospital at Stanford.

A pediatric hematologist/oncologist, Dr. Glader has made significant contributions toward an understanding of red blood cell destruction, cell membrane injurey and altered cellular physiology and biochemistry associated with hemolytic anemias, a common chronic anemia in children which can lead to retarded growth and other ailments.

The overall thrust of Grumet's research has been histocompatibility, which is the capability of cells or tissues to remain functional when grafted to another organism. Serving as associate director of the University Blood Center Program and director of the transfusion service at Stanford University Hospital, Grumet has been active in work relating to practical aspects of blood banking and to prevention of transfusion-acquired virus infection.

The 43-year-old Grumet is a native of New York City. He received his M.D. from from the University of Pennsylvania.

Simon, a specialist in the field of respiratory medicine, is studying the changes that occur either when oxygen depletion occurs or when a patient, who is experiencing respiratory distress, receives a high concentration of oxygen which may result in toxic side effects.

A native of Port Chester, N.Y., Simon, 40, graduated from the New York University School of Medicine.

Since 1979, he has served as chief of the respiratory medicine section as well as medical director of the respiratory therapy department and pulmonary function laboratory at the VA Medical Center. He also serves as director of the medical fiberoptic bronchoscopy service at the VA.

In addition to the tenure confirmations, the trustees also approved associate professor appointments in the clinical line for Ronald L. Ariagno in pediatrics, and for Bruce Parker in radiology and pediatrics.

Also, Peter Fessenden, Ph.D., was named adjunct profesor for teaching and practice in radiation therapy in the department of radiology.

(Editors: At the blood bank, please call Dr. Ed Engelman, medical director, or administrator Roger Svoboda, (415) 497-7903)

STANFORD—

A rare blood plasma was being sought for a 5-year-old girl suffering from an unusual kidney ailment at Stanford University Hospital.

Dr. Bruce Tune, a nephrologist, said the child required six units of rare type AB plasma daily in order to prevent permanent damage to her kidneys.

"If we receive the blood its possible that this child will completely recover," said Tune. "Without the blood, its likely that the child will suffer irreversible kidney damage," he added.

Rhoda Burns, a spokeswoman for the Stanford University Blood Bank, said the supplies of the rare AB blood type, present in only 4 percent of the population, had been nearly depleted during the 10 days the child has been hospitalized for the ailment called hemolytic uremic syndrome.

Tune said the disease usually follows an episode of diarrhea and results in complete kidney failure. Sufferers are unable to urinate, hence they are not able to eliminate waste products from their system.

Usually, the malady can be corrected, Tune said, by proper diet and a small number of transfusions. But the girl, identified only as a San Jose-area resident, is suffering so acutely that longer hospitalization with extensive transfusions are needed, he said.

Precisely how the transfusions correct the ailment is unknown, Tune said. "Apparently it either adds something the kidneys need, or it eliminates some poison in the kidneys, or perhaps both.

"All we do know is that transfusions seem to be effective at solving the problem in extreme cases such as this."

The rare kidney ailment occurs about 20 to 40 times a year in California, Tune estimated. The girl's case, he added, was one of the most serious he has seen.

-more-

While hospitalized, Tune said, the girl's body wastes are being eliminated through use of a kidney dialysis machine.

Burns said a nationwide search for AB plasma was underway, but doctors hoped that donors with AB blood would be willing to donate to the child locally at the Stanford Blood Bank, 800 Welch Road.

"If they live too far away, they should donate at a convenient blood bank and explain that it is for a child at Stanford," Burns said.

The spokeswoman said blood for the child would probably be needed for about six weeks for the child, "but since we've been using so much of this rare type, supplies around the country are being depleted. Therefore, we'll have a general need for AB even after the little girl recovers," she said.

Burns said the Stanford Blood Bank, which recently opened its donor facility, is equipped to make optimum use of the rare blood type through a procedure called manual pheresis.

Donors' blood will be drawn and the plasma will be extracted. The remaining blood components will be returned to the donor's blood stream.

This procedure, Burns said, enables donors to safely provide twice as much blood as they could if whole blood was drawn and retained. The pheresis procedure takes about one hour, she said.

Persons with AB blood are encouraged to call the Stanford University Blood Bank at (415) 497-7831 for an appointment.

STANFORD—

A filmless x-ray system intended to make certain diagnostic procedures safer while simultaneously making patient care more efficient was installed this week at the Stanford University Medical Center.

The new system, called digital fluoroscopy, employs a television camera which projects the image of the particular body part or tissue under study on a video screen. The picture is created from digital, or computer data, which allows the patient's picture to be stored on video or magnetic tape to be called up later by the doctor who can view it on a video screen.

"Within the next ten years, we expect systems employing video to totally revolutionize X-ray as we know it now," said Dr. Dieter Enzmann, head of the digital fluoroscopy program at Stanford.

The current system, manufactured by the General Electric Co., is expected to be in use treating patients by the end of October, Enzmann explained.

It was on display for approximately 400 persons attending the Sept. 14-15 Conference on Digital Radiography sponsored by the International Society for Optical Engineering, Stanford's Department of Radiology and the federal Bureau of Radiological Health.

Specifically, the device will be used initially for patients suffering from various blood vessel ailments.

Digital fluoroscopy enables good pictures of arteries to be recorded without the risk of inserting catheters (tubes) near the heart or brain. Such intrusions deep into the blood vessels to inject a dye could result in heart attacks or strokes.

In digital fluoroscopy, the dye, which is used to highlight the arteries, is injected into the veins in the arm, which is much less dangerous, simpler, and thus may be performed as an outpatient procedure, said Enzmann.

The individual picture produced of a blood vessel or soft tissue is not as detailed as the view produced from traditional catheterization.

-more-

But, Enzmann pointed out, the diagnostic capability is approximately the same, since the video console permits an imaging technique called subtraction.

First a picture of the patient is taken without a dye.

Then the same view is taken with the dye. The two views are combined on the screen in such a way as to eliminate unwanted structures (body parts), allowing the physician to observe areas of interest.

Hospitals may add the video camera and display console to their existing X-ray suite for about $200,000. Thus, Enzmann said, it is economically feasible now for use in many hospitals.

In addition, it provides potential efficiency and cost saving advantages for the hospital, patient, and the nation.

One of the largest savings, Enzmann said, is that hospital beds will be freed, because patients need not be hospitalized overnight as is necessary with catheterization.

"Eventually expensive X-ray film will be eliminated, and patient X-rays will be stored in a variety of ways, including digital and video disc and magnetic tape. Ultimately this could save hospital storage space and would be cheaper than film, but technological developments still are necessary for this development to become feasible," he said.

Within the next decade, Enzmann predicted it will be practical to transport X-ray pictures via cable to various locations, allowing a consulting physician in a nearby hospital, for example, to quickly view a patient X-ray transmitted to his own video terminal.

Other pioneering techniques in X-ray will also become increasingly available in the coming years.

One such system is "dual energy imaging," which is being used experimentally at Stanford under the direction of Dr. William Brody. This technique involves two nearly simultaneous X-ray photos of the same area taken at differing energy levels. The computer then constructs a picture on the video screen of the artery or material of interest to the physician.

STANFORD—

A noted neuroscientist, Dr. Dominick P. Purpura, has been appointed dean and associate vice president for medical affairs at the Stanford University School of Medicine.

The appointment, culminating a nine-month search by a faculty committee, was announced today, Sept. 14, by Dr. Lawrence G. Crowley, vice president for medical affairs.

Purpura's appointment will be effective sometime after January, 1982, when he completes his present commitments, Crowley said.

He praised Purpura as a distinguished investigator, teacher and dynamic administrator, with a deep commitment to medical education and concern for medical school curricular issues.

The 54-year-old scholar is currently a professor and chairman of the Department of Neuroscience, and director of the Rose F. Kennedy Center for Research in Mental Retardation and Human Development at Albert Einstein College of Medicine, the Bronx, New York. The center is an important institute, with both basic and clinical functions involving a number of medical school departments.

At Stanford Purpura will be the holder of the Carl and Elizabeth Naumann endowed chair as well as a professor in the Departments of Neurobiology and Neurology. He will also serve on the Board of Hospital Directors of Stanford University Hospital.

"I look upon the deanship as the most challenging opportunity of my professional career," wrote Purpura in his acceptance letter to Crowley. "Clearly, facilitation of the growth of such a distinguished institution as the Stanford University School of Medicine must be viewed as one of the most important missions in academic medicine today . . .

"I am certain I can effectively lead the faculty in their further pursuit of excellence in teaching, research, and patient care."

A graduate of Columbia College (1949), and Harvard Medical School (1953), Purpura completed his internship and part of his residency training at Columbia-Presbyterian Hospital in New York. He joined the faculty of neurological surgery at Columbia's College of Physicians and Surgeons in 1956 as a research physician. In 1967 he became professor and chairman of the Department of Anatomy at Einstein, advancing to his present administrative and academic posts in 1972 and 1974, when he founded the Department of Neuroscience.

His career is replete with honors, including a number of teaching awards, and the Lucy Moses Prize in Basic Neurology as well as the William G. Lennox Award of the American Epilepsy Society. He is president-elect of the Society for Neuroscience, and editor-in-chief of *Brain Research,* a major primary journal in the field, which he will continue to edit.

Purpura's most recent research has dealt with the study of human cortical development using the data and techniques of basic neuroscience.

He has applied this knowledge and techniques to the study of abnormal nerve cell development related to mental retardation. He was among the first to observe that the brains of children, who are mentally retarded with no known cause such as chromosomal aberrations, had structural abnormalities in their nerve cells.

He concluded that these structural distortions on the surface of nerve cells were the reason for the lack of cognitive development, and later others have confirmed his findings.

"Dr. Purpura's observations have been a seminal contribution in the area of mental retardation," said Dr. David Prince, professor and chairman of the Department of Neurology.

-more-

His work spans some 200 publications.

The new dean is no stranger to Stanford. He was visiting professor in Physiology in the early seventies. He taught basic neurology and neurophysiology. At the time there were discussions about the development of neurosciences program at Stanford in which he participated. The program became a reality in 1977 with the construction of the Sherman Fairchild Building.

Commenting on the search, Crowley said that a distinguished list of about 300 persons was considered.

"It was clear from the start that the faculty wanted a dean with an established academic and administrative record," he said. "Dr. Purpura emerged as the outstanding choice, and the consensus developed within the search committee and faculty and students was astounding."

The committee was headed by Dr. Jack Barchas, Pritzker Professor of Psychiatry and Behavioral Sciences.

Purpura comes to the Medical School at a time in which the posts of dean and vice president for medical affairs will be separate.

The posts were split in 1980 when Crowley was named vice president for medical affairs as part of a major reorganization of the Stanford University Medical Center and its units, the Hospital, Clinics, and the School of Medicine.

The reorganization, Crowley explained, recognizes the increasing complexities and responsibilities of the two positions and the need to be able to address the priorities of the Hospital and the School of Medicine on an even-keel basis.

Crowley's predecessor, Dr. Clayton Rich, held both positions when he resigned in 1979.

Among the dean's chief responsibilities will be the development and sustenance of the academic programs of the School in teaching, research, and patient care, including budget, allocation of academic space, and recruitment and nomination of academic chairmen and associate deans, Crowley said.

He will also be responsible for policies and procedures to insure the quality of academic programs, and the effective promotion of the Faculty Practice Program, and he will participate in a leadership role in the policy setting, planning and overall management of the Medical Center.

The dean also chairs the executive committee of the Medical School. Consisting of department chairmen and associate deans, the committee acts as the chief advisory body to the dean.

Purpura is married and has three sons and a daughter.

STANFORD—

"My most important concern is to find the way to becoming an effective dean, not necessarily loved, but effective, and to meet some of my own goals—making the School as good as it should be and perhaps even better."

Thus spoke Dr. Dominick P. Purpura, the newly appointed dean of the Stanford University School of Medicine, in a recent campus interview.

At 54, Purpura is of medium height, with brown hair, blue eyes, and a trim waist maintained by jogging 20-25 miles per week. His hair is thinning, and he wears glasses. He was full of thumping enthusiasm as he talked about the challenge of his new job.

"I've dealt with many deans in my 29 years of academic life," he readily admitted, "but I never felt they really understood the problems of basic scientists as I do.

"Everybody in academic medicine says this of deans. So the novel challenge that I face now is, Can I really do the job that I have always complained about?"

Purpura is convinced—and has said so on other occasions—that to be a satisfactory dean, one must do at least three things:

"First, he must be aware of not necessarily the consensus but the direction towards excellence that a faculty wants to take," he said.

"Faculties often do not know the way entirely, and the dean can facilitate that move."

He believes that because of his own experience as a scientist articulating those needs for years, perhaps he can now listen to the faculty a little better than a "professional" dean.

"Second, a dean must be aware that a School of Medicine is concerned with the teaching of medicine," Purpura said. "Too often some of the best medical school faculties have too remote a relationship with medical students and that leads to disillusionment for both students and faculty.

"I think it's important to put the medical student back at the central focus of concern in a medical school.

"Third, of course, apart from leading and guiding people towards their own ascertainment of excellence, is to recognize that a medical school, and Stanford in particular, is not on Neptune or Uranus.

"If the School were on an isolated planet or the Mojave Desert, there'd be no problem. It would be so contained that we'd develop in any way we saw fit. But the School is located in this community and it must develop its relationships in a proper and mutually beneficial way."

How was he considered for the Stanford deanship?

Purpura said he had lectured in the Physiology Department at Stanford in the early seventies.

"I concluded that the Medical School was a remarkable place and this was the one School that I would look into seriously, if I had the opportunity.

"But back at Albert Einstein School of Medicine I got busy with my own work. Eight years went by and I completely forgot about it. Then quite out of the blue last January I got calls from several people inquiring if I would be interested in being considered for the deanship.

"It didn't take me more than five seconds to respond that I was."

-more-

His interest in Stanford was two-fold, Purpura explained. "I knew for many years that the Medical School is a center of excellence. I also knew that my own career was moving more and more in the direction of research development and administration, although I had continued my own investigations."

Since 1972, Purpura has directed the Rose F. Kennedy Center for Research in Mental Retardation and Human Development in the Bronx, New York. For the past seven years he has also served as professor and chairman of the Department of Neuroscience, which he founded, at Albert Einstein College of Medicine.

His research at Einstein has concerned human cortical development using the techniques of basic neuroscience.

"I see the basic data coming out of neuroscience research as the only hope in our being able to understand the pathophysiology of developmental failure," he said.

Purpura and his colleagues have applied this knowledge and techniques to the study of abnormal nerve cell development related to mental retardation.

Specifically, he was one of the first to demonstrate that there were disorders of dendrites and dendritic spine structure in the brains of children with profound mental retardation. Most communication between nerve cells occurs through structures called synapses onto dendrites, threadlike extensions on the surface of nerve cells.

Purpura determined that the brains of children who are mentally retarded with no known cause such as chromosomal abnormalities, had nerve cells virtually devoid of the typical patterns of spine synapses that normally develop before birth.

He began to suspect that this problem was the basis for the lack of cognitive development, and later these findings have been confirmed by others.

"I went into research in medical school because it was as joyful as a hobby," he said. "And I feel I have been successfully funded for 30 years to practice my hobby. What a privilege and responsibility!"

"That's what in fact a good deal of basic research is for the individual—an exploration of the joy of discovery and doing things. For awhile I may give up some of that joy, but I think it's a minimal sacrifice."

Purpura, however, plans to teach. His lectures have dealt with integrative processes in the mammalian brain, and he is well-known for his ability to communicate clearly and to present difficult data in a simple, easy-to-understand manner.

"I love teaching," he said. "Back at Einstein I gave about 70 percent of the neurobiology course myself. I intend to be able to give some lectures, if invited, in the Departments of Neurobiology, Neurology, and Psychiatry at Stanford."

Purpura glanced at his watch. "Time," he said, "to go to my next meeting."

He was all smiles as he said goodbye. But it was clear that even though he doesn't become officially dean till next year, his job had already begun.

STANFORD—

Peter Wood isn't exactly sure what to say in a lecture entitled, *Dietary Intake of the Older Athlete.*

It's not that he doesn't know what older athletes eat. He's done studies, academic and personal, into what foods and diets seem to work best for active people.

He's got plenty to talk about, certainly.

"But I can't really think of any differences between the diet of a 65-year-old runner and a 20-year-old runner. The differences in a desirable diet are quite minimal," he states carefully. In fact, Wood, who has been running for 40 of his 52 years, says he can't think of a single thing older runners should eat differently from their more youthful compatriots, except that children and adolescents need extra calcium, other minerals and vitamins for growth.

Yet Wood, who estimates he's run about 100 marathons at times ranging down to a respect-demanding 2 hour and 45 minutes, will deliver his talk on diet for older athletes Sept. 25. It's the final morning of a two-day seminar entitled "Nutritional Determinants in Athletic Performance."

The symposium is being held at the Sheraton Palace Hotel in San Francisco and is jointly sponsored by the Stanford Heart Disase Prevention Program (SHDPP), the American College of Sports Medicine and the Shaklee Corp., a manufacturer of nutritional products and food supplements.

Coaches, trainers, teachers, physicians and scientists will exchange the latest research findings on the role of nutrition, fluid intake and body composition on athletic performance.

Wood, deputy director of SHDPP, firmly believes that diet should relate directly to exercise and not the age of the participant.

"If someone is running a marathon, he's going to need a lot of carbohydrates whether he's 20 or 80,"Wood emphasizes.

But he also cautions:

"Remember we're talking about athletes. You can't compare the diet of a 70-year-old runner with a totally sedentary 70-year-old."

Wood, who ran this year's Boston marathon in just over three hours, said he prepares for races using a modified form of a technique called carbohydrate loading.

About one week before a major race, Wood says he takes about a 25-mile run in the Palo Alto hills near his house.

"I become exhausted, and the glycogen (the form in which people store body sugar or energy) content of the muscle drops significantly. I then eat plenty of carbohydrates until the race.

"Being British (Wood has been in California about 20 years) I do enjoy sugar, but I wouldn't recommend that. Any starch will do.

"Just about the time the race starts, the glycogen is building to a peak. This gives a boost at the starting line, a sort of rebound effect."

Some athletes further deplete their glycogen level by restricting their carbohydrate intake for a few days after their exhausting pre-race workout. Then they eat extra carbohydrates for just a few days before the race.

"But I think that's a bit much, and just might possibly be harmful," Wood says.

-more-

The runner and scientist—his specialty is lipid chemistry—cautions that techniques such as carbohydrate loading are fine for athletes when they solve certain endurance problems.

"But they certainly aren't the cure for everything. Carbohydrate loading isn't going to solve a mechanical defect such as helping someone's legs get longer or their lungs breathe easier from smoking, to cite a few obvious examples."

Athletes burn signficantly more calories than sedenatry persons, Wood explains, "so consequently a vigorous exercise program is sometimes the least painful way to diet."

As for general dietary guidelines, Wood recommends what most experts have been suggesting for at least a decade: less fat, salt and cholesterol; more fiber and carbohydrates.

"But if I only had 20 seconds to tell athletes what they should consume, I should say, 'before and during exercise in hot weather, drink plenty of water.'"

Meetings for the two-day symposium begin at 8:45 Sept. 24.

Topics include a presentation on the latest research into the role of carbohydrates and fats in running, what drinks will maximize athletic performance, the role of vitamins, and the consequence of rapid fluid and weight loss on health and fitness.

Co-chairmen are Dr. William Haskell of SHDPP and Dr. James Scala, Shaklee vice president of Science and Technology.

STANFORD—

The role of diet in athletic performance is the subject of a symposium scheduled Thursday and Friday (Sept. 24-25) at the Sheraton Palace Hotel in San Francisco.

Coaches, trainers, teachers, physicians and scientists are to spend the two days exchanging the latest research findings on the role of nutrition, fluid intake and body composition on athletic performance.

Entitled, *Nutritional Determinants in Athletic Performance*, the symposium is sponsored by the Stanford Heart Disease Prevention Program (SHDPP), the American College of Sports Medicine and by Shaklee Corp., manufacturer of nutritional products and food supplements.

Special lectures include a special presentation on *Sports Anemia: Its Influence on Athletic Performance* by Russell Pate of the University of South Carolina, and *The Diabetic Patient and Athletic Peformance* by Arthur Leon of the University of Minnesota.

Also included will be presentations of general interest on the latest research on the role of carbohydrates and fats in running, what drinks will maximize athletic performance, the role of vitamins and minerals, and the consequences of rapid fluid and weight loss on health and fitness.

Lecturers include David Costill of Ball State University, Gail Butterfield of the University of California at Berkeley, Peter Wood of SHDPP and James Whittam of Shaklee.

For further information contact symposium co-chairman Dr. William Haskell of Stanford (415) 497-6254, or Whittam at Shaklee, (415) 887-5136.

STANFORD—

The first use of synchrotron radiation to obtain X-ray pictures of blood vessels in animal hearts was reported by Stanford University scientists Monday, Sept. 14.

The novel application of synchrotron radiation to medicine, according to Dr. E. Barrie Hughes, "offers a new approach to arteriography of the coronary arteries by non-invasive means."

The new technique, developed by grants from the Henry J. Kaiser Family Foundation and the William Randolph Hearst Foundation, may turn out to be, the scientists believe, one of the most important advances in X-ray diagnosis since Wilhelm C. Roentgen, a German physicist, discovered the X-ray tube in 1895.

Hughes is project director and senior research associate at Stanford High Energy Physics Laboratory. He discussed the potential uses of synchrotron radiation in medicine at an International Conference on Digital Radiography at Stanford University Medical Center.

Synchrotron radiation, obtained by whirling electrons in a ring at nearly the speed of light, produces X-rays of enormous intensity that can be finely tuned. This form of radiation has been used for analytical research in surface physics, biochemistry, solid-state physics, and structural biology. But this is the first time, according to the scientists, that synchrotron radiation has been studied as a source for producing clear pictures of small and large blood vessels in the heart, brain and other parts of the body.

The technique so far, Hughes reported, has been studied in phantoms, objects that mimic body structures, and in excised calf and pig hearts injected with a contrast agent such as iodine.

In patients the procedure will involve two X-ray pictures following a simple injection in an arm vein. It would be done on outpatients and would provide an alternative to catheterization, an uncomfortable and expensive test associated with risks and requiring several days of hospitalization.

Another possible use of the technique would be in mass screening for coronary and cerebral artery disease much as the X-ray is now used to detect tuberculosis. The present methods of visualizing coronary and cerebral arteries are too costly in terms of risks and dollars. Their use is limited only to those patients suspected of having advanced disease, the scientists believe.

According to Hughes, attempts to develop non-invasive methods in angiography have suffered from the use of conventional X-ray sources which are too weak to provide a truly monochromatic or single-color X-ray needed for the procedure. The conventional Roentgen tube emits white light which also suffers from a scattering effect as it penetrates tissue structures.

"A synchrotron X-ray beam, on the other hand, is capable of providing an X-ray intensity entirely adequate to record projected images even after transmission through thick body sections," Hughes explained.

The Stanford investigators are performing their experiments at the Stanford Synchrotron Radiation Laboratory (SSRL) adjacent to an electron storage ring called SPEAR located at the Stanford Linear Accelerator Center. SPEAR, in combination with special magnets, called "wigglers," developed by SSRL scientists to maximize the production of synchrotron radiation, represents a totally new source X-rays with more than 100,000 times the intensity of the radiation emitted from the largest X-ray tube.

- more -

According to Dr. Arthur I. Bienenstock, director of SSRL, "It is the development of wiggler magnets that has made the medical experiments possible."

Through a "window" in the storage ring, the scientists intercept the beam of X-rays with a pair of special crystals called monochromators, also built by SSRL scientists. The angle of the crystals can be adjusted to select a single-color X-ray frequency most sensitive to iodine.

Using miniature electronic detectors, the scientists take two X-ray pictures of the organ that has beeen injected with iodine. The pictures can be displayed on a television monitor or oscilloscope in graph form. The two pictures display all the blurry features normally presented by soft tissue and bones in conventional X-rays.

But when the two pictures are fed into a computer the scientists can suppress the information derived from tissues, and maximally enhance information related to the iodine.

The result, Hughes said, is images that can be recorded in sharp focus despite arterial motion. The intensity of the X-ray beam permits short time exposures well below that of a conventional X-ray, and the scattering effect is all but eliminated.

The next stage of their research, the scientists announced, will involve studies in animals and a small number of patients. This work, however, will probably not begin until next summer when a new X-ray beam line, wider than the present one in the storage ring, is constructed. This would include a patient examination area within the Stanford Synchrotron Radiation Laboratory.

In the future one of the major obstacles in the use of synchrotron radiation in medicine will be the high cost of constructing facilities. But Hughes said, "Rapidly developing technologies are making useful beams available at more existing centers and reducing the potential size and cost of future facilities designed expressly for medical work."

There are about six synchrotron storage rings currently available in the United States and operating in connection with large accelerators built for basic physics research.

The research team is composed of investigators from the departments of Physics and Electrical Engineering, and the Stanford University School of Medicine.

Principal investigators are Dr. Edward Rubenstein, professor of clinical medicine and Medical School associate dean for postgraduate education, and Nobel Laureate Robert Hofstadter, Max H. Stein professor of physics.

Other collaborators include Lorna E. Campbell, Randolph L. Kirk, Thadeus J. Krolicki, Jennifer P. Stone, Steven Wilson, Dr. Herbert D. Zeman and Professors William R. Brody, and Albert Macovski.

Dr. Albert C. Thompson of Lawrence Berkeley Laboratory designed the special detectors utilized in the project.

STANFORD—

A new artificial pancreas is being used at Stanford University Hospital in efforts to help insulin resistant diabetics.

Dr. Michael Greenfield, an endocrinologist, said blood sugar level has been successfully controlled so far in six diabetics who volunteered to participate in a pilot study.

The experiment was started about six months ago under a grant by the National Institute of Health and the Nora Eccles Treadwell Foundation. Dr. Gerald M. Reaven, professor of medicine, is the principal investigator.

The artificial pancreas is a mechanical device which permits the patient's insulin needs to be monitored on a minute-to-minute basis. The machine calculates and then administers the precise insulin dose needed at various times of the day to maintain proper blood sugar level.

About 10 million Americans suffer from diabetes, a disorder in which the body is unable to properly oxidize carbohydrates—specifically blood sugar—because either the pancreas fails to produce sufficient insulin or the body is incapable of utilizing its existing insulin supply. The amount of insulin needed at any given time is highly variable, and depends on such factors as food intake (which supplies glucose or sugar) and amount of exercise.

In the Stanford program, patients are hospitalized for about two weeks. Volunteers are connected to the mechanical pancreas, where for 24 hours blood in minute quantities is drawn from one arm and analyzed by the machine. The device, which costs $50,000, vaguely resembles in size and appearance a battery charger used by service stations.

"The blood is analyzed for glucose level every 10 seconds and the appropriate insulin dosage is thus computed. Then the machine injects insulin into the other arm at the precisly computed dosage," explained Robert Solomon, a research fellow.

Greenfield said the technique "is particularly significant for the millions of non-insulin-dependent diabetics who previously have been treated unsuccessfully with other drugs.

"There are people whose bodies produce an average or only slightly below average amount of insulin. What happens, though, is that for some reason their system is unable to use their own insulin to control the amount of blood sugar.

-more-

2-2-2 "Physicians in the past sometimes gave them massive doses of insulin in order to try and control the diabetes. But that approach was not effective, because we didn't know how much the patient needed at a particular time of the day," Greenfield added.

During the past decade, these older diabetics have been treated with drugs intended to help their bodies utilize their own insulin. But Greenfield explained that these drugs, while often offering temporary relief, may not sometimes provide any longterm benefits.

(In contrast, diabetics whose bodies fail to produce sufficient insulin have been treated successfully for many years with insulin injections. Because their insulin needs are smaller and more predictable, doctors have found it easier to prescribe proper dosages for these patients, who usually are younger than the insulin-resistant diabetic.)

Solomon said that the amount of blood used during a two-week hospitalization would be about the same as a single blood bank donation.

About 21 artificial pancreas machines currently are being used nationally, but Greenfield said he believes Stanford is the only facility using the gear for treatment research into non-insulin dependent diabetes.

Greenfield and Solomon said the current volunteers all have shown significant improvement in their blood sugar as they are continued to be monitored by their private physicians and the Clinical Research Center at Stanford University Hospital.

Eventually, the researchers hope that a miniaturized version of the artificial pancreas might be developed, so that a patient's insulin dose might continue to be monitored and administered. But Greenfield said the predictions based on the two-week monitoring seem to work effectively for the group tested so far.

Solomon and Greenfield both said current research would have to be expanded if scientists are to learn why some people build up a resistance to insulin or if the resistance is the preexisting condition which hinders the body's ability to burn blood sugar or produce insulin efficiently.

Doctors, who hope to complete the study in about a year, are searching for additional volunteers.

Criteria include persons suffering from diabetes who are otherwise in reasonably good health. They should never have been treated with insulin before. The researchers would prefer persons who are not more than about 25 percent overweight.

The volunteers will be treated without charge, including free insulin supplies, Greenfield said.

Persons or referring physicians who wish to contact the program may call Greenfield or Solomon or Claude Lardinois at (415) 497-6973 or 497-6054.

(If you wish to call the Stanford University Blood Bank directly, please call Deborah Spector at (415) 497- 6795)

STANFORD—

When you sign a contract to work with Deborah Spector at the Stanford University Blood Bank, one thing you don't get is money.

Spector, hired three months ago to set up a volunteer program for the blood bank, is looking for about 25 people who will perform a plethora of tasks without pay at the recently opened donor center.

But, said Spector, that doesn't mean she's looking for amateur or casual performances, and that's the reason for the contracts.

"We're trying to do everything as professional as possible, hence we developed the idea of contracts for our volunteers," she said.

"We'll spell out very specifically what we expect of our volunteer workers and what they might expect of us," she said.

One thing volunteers might hope for, of course, is a sense of satisfaction from helping people.

"And I think we're offering a real chance for our volunteers to feel part of a team—to feel as if they belong to a vital work environment. There are going to be very few distinctions between our paid and unpaid staff," Spector said.

But in addition to satisfaction, Spector said volunteers will be receiving some very practical benefits, particularly persons seeking to enter or reenter the job market.

"They'll be gaining work experience, and they'll also be getting a reference from us."

Students might also receive work-study credit if it can be arranged with their high school, college or technical school, she said.

Each volunteer will be asked to tour the facility at 800 Welch Road before deciding what task they will perform.

Needs include persons to assist with registration and scheduling of about 65 donors daily. Other persons are needed to drive blood donations to the Stanford Medical Center laboratory for processing, record keeping, helping donor nurses in a myriad of ways, or using telephones to recruit donors.

"One of the most important things we do around here is make donors feel comfortable," said Spector. "The main qualification," she said, "is a willingness to give of yourself, help others and be part of a team.

"But we certainly aren't going to rule out people with specific technical skills either, especially since the complex treatments, including organ transplants underway at Stanford University Hospital, require processing equipment and techniques not ordinarily found at many blood banks."

All of the blood is used at Stanford University Hospital, exclusively for patient care, unless the donor is informed in advance that his blood is needed for Medical Center research.

In order to keep the constantly needed supply of blood flowing, Spector said she is particularly anxious for volunteers of varied backgrounds.

"Our donors come from all walks of life. In order for them to feel as comfortable and at home as possible, it's vital that our volunteers also represent as wide a spectrum of our community as possible," she said.

Handicapped persons are particularly urged to apply.

"I think there are quite a few handicapped persons out there who are truly interested in doing volunteer work, but who feel reluctant because no one ever asks them.

"Well, we're asking," Spector said.

And lest anyone think that volunteering at the blood bank is purely for women, Spector adds:

"We've ordered quite a few uniforms for men."

To get a uniform—given to each volunteer—or to secure further information, call (415) 497-6795.

STANFORD—

Volunteers are needed to help determine how the human process of aging affects the way in which different drugs are metabolized by the liver.

A group of Stanford researchers headed by Dr. Terrence Blaschke, chief of the Division of Clinical Pharmacology, is conducting a study on how the liver breaks down different types of drugs and how this process changes with age.

The three drugs being tested are amobarbital, oxazepam, and isoniazid.

Volunteers in the study are administered small doses of each drug, each on a separate day. Blood and urine samples are collected throughout the week, which subjects spend in the Clinical Research Center.

"There are different pathways by which the liver eliminates these drugs," says Blaschke, "and we think that one of the pathways will change with age whereas the other two may not."

If this is true, he explains, it would affect dosage prescriptions of different drugs, depending on their pathways, for patients of varying ages.

The doses of drugs administered, explains Kathy Turner-Tamiyasu, the research nurse involved in the project, pose only minimal risks.

"The only really possible problem is an allergic reaction, which we can never predict." The other risks are described in detail on the consent form.

Volunteers must be healthy, white women, aged 40 to 80. They should be non-smokers who take no medications except birth control pills or Premarin. All subjects will be compensated.

The reason for using white women only, explains Blaschke, is to provide for homogeneity. "Also," he says, "we wanted to look at hormonal changes both pre- and post-menopause."

Anyone interested in volunteering or obtaining further information should contact Turner-Tamiyasu, at 497-5266.

(EDITORS: A longer, featurized article about the artificial pancreas research at Stanford University Medical Center is available if not included).

STANFORD—

A Stanford University Hospital program is searching for volunteers willing to undergo treatment in an experimental program studying adult onset diabetes.

Dr. Michael Greenfield, an endocrinologist, said the program involves the use of a mechanical monitor which during a two-week period develops a precision profile of certain diabetics' insulin needs.

Volunteers should be adult-onset (non-insulin-dependent) diabetics who never before have been treated with insulin. Greenfield said potential volunteers should be otherwise in good health and within about 25 percent of their ideal body weight.

Selected volunteers will be admitted to Stanford University Hospital for two weeks, where their blood will be analyzed on a minute-by-minute basis using the artificial pancreas. After their release, volunteers will be followed closely by the Stanford researchers and their own physicians.

All costs, including hospitalization, insulin and followup visits, will be provided free to volunteers under a National Institute of Health grant. Six volunteers, who have been involved in the program for up to six months, have found their diabetes successfully controlled, Greenfield said.

Volunteers or physicians wishing to refer patients may call Greenfield, Solomon or Claude Lardinois at (415) 497-6973 or 497-6054.

STANFORD—

An election is scheduled Sept. 18 to decide whether about 90 Stanford University Hospital employees want to be represented by Local Union No. 39, International Union of Operating Engineers, AFL-CIO.

Eligible to vote are the crafts and communications employees and biomedical technicians formerly represented after 1972 by an unaffiliated hospital employee organization, SUMCEDA, an acronym for Stanford University Medical Center Engineering Department Association.

The election will be held from 7 to 9 a.m. and 3 to 5 p.m. at locations to be determined at both the main Hospital and Hoover Pavilion.

In a Nov. 30, 1979 election SUMCEDA scored 39 votes, Local 39 got 36, and 5 workers voted for no union. In addition, four ballots were challenged and the election results were suspended.

After the election Local 39 filed objections and an unfair labor practice charge against the hospital. These actions resulted in more than one year of proceedings before the National Labor Relations Board. In early 1981 Local 39 dropped its charge and all objections.

While the results remained in limbo, SUMCEDA's leadership wrote asking to withdraw as the bargaining unit.

Norm Keltner, acting SUMCEDA president, said he wrote the letter because the workers were "dissatisfied with SUMCEDA's ability to bargain with management.

Keltner served as an official election observer for Local 39 in the 1979 election.

Following an investigation the NLRB ruled June 30 that SUMCEDA'S request to cease representing the workers was legitimate and represented the wishes of the membership. The NLRB then ordered a new election.

Don Thomas, hospital personnel director, in a Sept. 1 letter to the employees eligible to vote, sait the hospital administration felt it owuld be a mistake to bring Local 39 into the hospital. He added the hospital would provide the employees with accurate information on the issues involved before the election.

Dan Robinson, assistant director of personnel, said market adjustments have been made to the formerly SUMCEDA-represented employees' salaries on Aug. 30, 1980 and 1981, along with yearly wage adjustments for other hospital employees.

STANFORD—

A prototype X-ray system which its developers believe could radically improve certain diagnostic procedures is expected to highlight an International Conference on Digital Radiography scheduled at Stanford University Medical Center Sept. 14-16.

The device, which is based on the technology used for the CAT scanner, is the substance of a system called dual energy digital radiography.

Dr. William Brody, director of Stanford's Advanced Imaging Techniques Laboratory and conference chairman, said the system employs two beams of X-ray. The simultaneous images are compared and analyzed by computer and then projected on a television screen.

Unlike traditional X-rays, which give a single picture forever frozen onto film, the use of a console and a TV screen permits physicians and/or technicians to adjust the picture so that particular organs, or even tissue, may be highlighted. This, said Brody, provides doctors with a heretofore unavailable diagnostic picture.

The images recorded by camera are fed into a computer, so that they may be converted into verbal data or numerical tabulations in addition to pictures on the video screen.

Tissue or blood vessels may be viewed without catheterization, an often risky procedure which can trigger stroke or other vascular injury.

Stanford researchers have been using the machine on patients with vascular problems on an experimental basis, but another system called digital fluoroscopy—which also uses video equipment to construct X-ray pictures—is to be set up while the conference is underway.

Digital fluoroscopy, unlike dual energy radiography, is commercially available, and can be placed in a large hospital setting quickly.

In fact, Brody said the system is expected to be used in patient treatment at Stanford by the end of September.

A major difference between digital fluoroscopy and X-ray is that the dual energy gear is capable of isolating the particular organ or tissue needed for study with one picture. With fluoroscopy, the patient must be photographed twice, creating the risk that the picture will not be a precise match and might be blurred.

The first picture is taken without a dye or contrast medium. The second picture is taken after a dye is injected, and results of the two pictures are compared. Even though with fluoroscopy a dye must be injected, no catheterization is needed, thus making it far less risky than traditional X-ray.

Techniques currently are not developed to the point where fluoroscopy can replace catheterization in all cases, since picture quality may not always be as desirable. However, Brody feels the procedure is clearly the direction in which X-ray is heading.

The conference at Stanford starts at 7:30 a.m. Monday, Sept. 14. Group meetings are to be held in Fairchild Auditorium at the Medical Center.

Brody said that sessions are intended for both medical personnel and scientists involved in the techniques of developing digital radiography and its application to patient diagnosis.

Sponsors include the Advanced Imaging Techniques Laboratory of the Department of Radiology, as well as the International Society for Optical Engineering and the Bureau of Radiological Health.

A one-day tutorial course, An Introduction to Digital Radiography, precedes the main conference on Sunday, Sept. 13.

STANFORD—

Stanford University School of Medicine recently announced the selections of this year's Andrew W. Mellon fellows, Agnes Axtell Moule faculty scholars, and William H. Hume scholars.

The Mellon fellows were chosen in accordance with a three-year $400,000 grant awarded to the School of Medicine in 1979.

The medical scientists receiving funds from the Mellon Foundation in New York are Richard Britt, M.D. (surgery), Dieter Enzmann, M.D. (radiology), Brian Hoffman, M.D. (medicine), Robert Marcus, M.D. (medicine), Vera Morhenn, M.D. (dermatology), Ron Rosenfeld, M.D. (pediatrics), Peter Sargent, Ph.D. (structural biology), Gary Schoolnik, M.D. (medicine), Carla Shatz, Ph.D. (neurobiology), Howard Shulman, Ph.D. (pharmacology), Jeffrey Sklar, M.D. (pathology), and Lawrence Steinman, M.D. (neurology).

The Hume fellowships are funded by a $5.6 million gift left to Stanford by the late William Mansur Hume of Woodside. The 1981-82 Hume Faculty Scholars are Helen Blau, Ph.D. (pharmacology), Eric Knudsen, Ph.D. (neurobiology), Bruce Ransom, M.D. (neurology), Stephen Shochat, M.D. (surgery), and Douglas Wallace, Ph.D. (genetics).

As stipulated in Hume's will, all the fellows are engaged in basic biomedical research.

The Moule fellowships were set up through bequests made by the late Manley A. Moule in memory of his mother, who died of cancer in Palo Alto in 1939. Moule, a 1917 Stanford graduate, requested that the money go towards cancer research.

The Moule recipients are Ann Arvin, M.D. (pediatrics), Jerome Burke, M.D. (pathology), Barbara Carroll, M.D. (radiology), C. Norman Coleman, M.D. (radiology), Richard Hoppe, M.D. (radiology), Anthony Howes, M.D. (radiology), Robert Kessler, M.D. (surgery), Lawrence Korn, Ph.D. (pathology), Jane Marmor, M.D. (radiology), Peter Moskowitz, M.D. (radiology), Peter Parham, Ph.D. (structural biology), Gordon Ringold, Ph.D. (pharmacology), Branimir Sikic, M.D. (medicine), F. Graham Sommer, Ph.D. (radiology), and Roger Warnke, M.D. (pathology).

Both the Hume and Moule fellowships provide for some salary support, $1,000 for laboratory or teaching expenses and $500 for travel to scientific meetings.

STANFORD—

The Department of Dietetics has prepared a 45-minute nutrition workshop specifically designed for Stanford adult outpatients who are undergoing cancer treatment. The workshop was developed to help cancer patients obtain and maintain good nutritional status, explains Jane Woeckener, assistant director of Dietetics/Nutritional Services, because malnutrition can influence response to cancer treatment.

The workshop will be conducted by Kristine Birge, R.D., M.S., a clinic nutritionist. During the workshop, patients will participate in determining their individual ideal weights, protein needs, caloric requirements, nutrient needs, needs for vitamin supplementation, and plans for dietary improvement.

The total cost of the workshop for each participant is $10. A copy of the Department's new publication, "Nutrition for Cancer Patients undergoing Radiation and Chemotherapy," will be given to each participant.

The first workshop is scheduled for Sept. 17, from 9 to 10 a.m., in room E003. Subsequent workshops will be conducted weekly with the time and day varying each week to maximize patient participation. Workshop schedules are posted in the Oncology and Radiation patient waiting areas, or can be obtained by calling the Nutrition Clinic.

The Department of Dietetics' belief, says Woeckener, is that this will be a "successful, self-supporting workshop that can be of significant benefit to patients receiving outpatient cancer treatment."

Any questions about the program should be addressed to Kristine Birge, who can be reached at 497-5440.

STANFORD—

Many activities which Stanford's Rosemary Watt and Suzanne Miller had anticipated during their recent nursing oncology tour of the Soviet Union should never have been planned.

They know that now but explain that much of the disappointment that surrrounded their attempt at a professional exchange with Russian nurses stemmed from their own naivete towards the "stigmas" attached to both cancer and the nursing profession within the USSR.

"Many times it was like beating a dead horse with the things we were trying to do," said Watt, an enterostomal clinical nurse specialist and co-leader of the nursing tour.

Prior to the 14-day trip, Watt and Miller had anticipated discussing cancer patient care with Soviet physicians and nurses. The tour, presented by the Professional Seminar Consultants, Inc., was designed as a continuing educational experience for the more than 80 nurses in the group congregated from around the nation. Watt and Miller were asked to present papers to the nurses, some of which were to be presented to Soviet nurses as well.

But not one socialist nurse attended any of the six lectures given in the five republic capitals they visited. The private discussions of cancer patient care never happened nor did the opportunity to observe nurses caring for or physicians treating cancer patients.

When asked why, Miller could only shrug. "We didn't ask a lot of questions about why we couldn't. We just made it known that we wished to meet with Russian nurses and talk with them."

"The status of nurses in Russia is such that this was not appropriate behavior," surmised Watt. "Presenting papers to nurses is just not done there."

Miller, a clinical oncology nurse educator here at the Medical Center, noted that nurses in the USSR don't make the type of nursing judgments common in America. Because of nurses' subordinate role there, Watt and Miller were given the chance to talk with only one nurse in the three cancer institutes and one hospital they visited.

The one discussion was held with a head nurse in the operating room where, as far as Watt and Miller could tell, she performed many of the same duties as surgical nurses do here. Nevertheless, the conversation was allowed only with a physician present, who, as the Americans recall, continually interrupted the nurse and answered questions for her.

(Though an interpreter accompanied them at all times they cautioned that there were problems with translation, as the interpreter was "not necessarily medically oriented.")

Many of the touring American nurses got a better understanding of the feeling for their profession from talking with one nurse of Russian descent who was along on the tour. She told her colleagues that while she was growing up, there came the dreaded day she had to tell her Russian-raised parents she wanted to be a nurse.

-more-

"They responded as though she told them she was going to be a prostitute," said Watt.

"The role of nursing as we know it was just not a part of the culture in which we found ourselves," said Watt. " You had to face reality and deal with it as it is."

One word that creates even more negative feelings than nursing and is seldom allowed in Soviet households is "cancer."

"It's treated (in attitude) like leprosy," said Watt, adding that even those patients who have it rarely, if ever, hear the word mentioned.

"Cancer patients there don't get told their diagnosis," said Miller. "They may suspect but even those in the cancer institutes say to themselves, 'I'm here because my doctor works here and that's all. Everybody else here has cancer but I don't.' "

Watt and Miller believe that the evasion surrounding the illness is similar to the attitude towards the disease in the U.S. during the 1940's and 50's. But despite the design of the tour, they never did observe cancer patient care by nurses and received only brief, partial tours of the cancer institutes.

"The staff within the general, or emergency hospitals as they are called, were marvelous to us," said Watt. "They showed us patients and equipment and graciously answered our questions. It was just the cancer institutes that shut their doors."

As far as cancer treatment goes, Miller said that though she was told they did use chemotherapy, she never did observe it in use. During their tours of the institutes they only saw halls and the diagnostic areas.

"All of the presentations in the cancer hospitals were done in an auditorium with the physicians at podiums," said Miller.

She said one nurse was going to be given a tour of the pediatric ward by a physician in one of the cancer institutes when a senior doctor stepped in the way, saying it wasn't possible because the ward was under construction.

"It's in a way difficult to sift out what was real and what they wanted you to see," said Miller.

Despite the lack of extensive tours, at least one nurse got a first-hand account of general nursing care, as, while on the trip, she suffered an acute appendicitis attack.

The care administered following her appendix-removal surprised Watt and Miller. No intravenous feeding was given despite her nausea, and the nurses recall that her blood pressure was never taken.

"The only physical measurement that the nurses did was to take her temperature," remembers Watt.

The hospitalized nurse later reported that about the only responsibility she could observe nurses having on a regular basis was giving out medicine. Watt added, however, that she did hear they were also involved in ambulation, assisting bedridden patients to walk, and catheterization, inserting a catheter into the bladder.

They also noticed the medical staff there often reused non-disposable brown rubber IV tubing and IV bottles, a common practice here in the states during the second world war.

-more-

"Generally speaking, even though some areas of care may be more sophisticated, my impression is that they're about thirty years behind," contended Watt.

The trip began in Moscow on July 14, and continued through the cities of Tbilisi, Erevan, Baku and Kiev, all capitals of their respective republics. Ninety-one people, including some family and friends, went on the tour. Three were from Stanford University Medical Center, while two others were from Children's Hospital at Stanford.

Not all of the trip was business, however, as nurses spent time shopping, sipping cognac and savoring borscht as well. In addition to visits to the Kremlin, Red Square and St. Basil's Cathedral, cultural activities ranged from attending a Moscow circus to swimming in the Caspian sea.

They enjoyed great freedom during their trip and while avoiding any political questions, resolved many of their own presumptions about Soviet life. As independent winemakers, Watt and Miller found a personnal interest in Soviet wines.

Miller said that on one guided tour they were shown a bell that was so big they couldn't lift it out of the pit it was formed in, and a cannon that was said to be so big that if it were ever fired it would blow itself up.

Miller said that their tour guide added, "We are like you in America, we like things bigger and better. We don't always make them better but we try to make them bigger."

Overall, Watt and Miller were excited about their experiences in the Communist country and were satisfied with their professional exchange with the medical staff. Watt felt that many of the setbacks in their plans were due to the size of the group they were traveling with. If just the two of them were to go back, she feels even the cancer hospitals would probably be more open to their questions and requests.

They also were pleased with the gift exchanges between the health care representatives of the two countries. Watt said they gave the physicians Russian-translated copies of the papers they presented during the trip and samples of American medical supplies. In return, the Soviet physicians presented them with pins and postcards of the area and, in one instance, a picturesque book, in Russian of course.

(EDITORS: Elvia Garwood, director of the Hospital Modernization Program, is available at (415) 497-7474).

STANFORD—

Preparation of detailed designs and licensing applications have been authorized for the largest construction project in the history of Stanford University—the Hospital Modernization Project (HMP).

The Board of Stanford University Hospital Directors resolved at an Oct. 23 meeting to authorize the Seattle-based architectural planning firm of Naramore, Bain, Brady and Johanson (NBBJ) to begin Nov. 1 drawing up detailed schematic plans for the project. NBBJ already has prepared a predesign summary outlining proposed changes and has opened a Palo Alto office for the project.

The board's action also authorizes the application of a Certificate of Need (C.O.N.) from the state of California by Feb. 1. The procedure is required of hospitals seeking to renovate or add to their facilities, and in essence ensures that a community need exists for the alteration or addition.

The HMP is estimated at about $70 million in construction costs. The total pricetag will depend on market conditions at the time money is borrowed. In Oct. 1980, the board authorized a total cost ceiling, including financing, of $114.8 million.

HMP Director Elvia Garwood explained that the project is intended to augment the level of medical services given without the need to seek an increase in the hospital's license for 663 beds.

"People come to Stanford University Hospital because of the unparalleled quality of our medical care," Garwood said. "When the modernization is completed, we're hoping they will come here because of the outstanding level of comfort and convenience we'll be offering as well."

The board's action this month maintains the staggered design and construction timetable on schedule.

The current first stage, which began with pre-design planning July 1, is to convert large segments of unimproved shell space into patient treatment and diagnostic facilities for radiology and cardiology, as well as expanded capacity for pharmacy, the transfusion service, dietary, surgical pathology, as well as various support functions, such as materials management (supply). This stage is expected to be completed by June 1984.

Additional stages, involving new construction and remodeling of current facilities, would be completed by March 1987.

-more-

2-2-2

The package calls for construction of 44 acute pediatric medical-surgical and intensive care beds, about 100 medical-surgical beds and 66 intensive care beds. Some of the beds will replace those currently in use at the aging Hoover Pavilion annex (formerly Palo Alto Hospital), while other beds will be moved from existing units at the Main Center.

"We are hoping that 35 percent of all beds will be in single rooms," Garwood said, adding that currently two beds have been placed in some rooms intended for use as singles, and many rooms intended for four persons are housing five patients.

"Our goal is to create more space for individual patients, and since this is of course a major teaching hospital, additional room for bedside examinations will enhance the learning opportunities," Garwood said.

Much of the modernization will involve new construction rather than remodeling, Garwood said, because the costs of bringing some units up to the most modern standards would be higher than replacing them.

For example, the architects have estimated it would have cost about 10 percent more to remodel rather than replace the 14 operating rooms currently in use, Garwood said.

The new surgical suite will house 24 operating rooms. Besides cost, Garwood said that replacement was chosen in lieu of remodeling because insufficient space existed at the present site to expand. The old space will be converted into a respiratory, physical and occupational therapy facilies but will remain in use as operating rooms until the new suite is completed, Garwood said.

The plans call for more comfortable waiting room facilities, updated equipment and a floor plan which will allow more efficient movement of patients, personnel and equipment.

The HMP's new construction will occur to the east of the current building, and the main entrance would be moved into the new construction which will also contain the lobby, gift shop and admitting areas. The cafeteria is to be remodeled and additional food service areas will be provided.

Two alternative final designs are being considered, Garwood said, one offering a slightly more horizontal design which would allow a wider range of critical care functions to be placed contiguously on the same floor. The alternative design would be more compact and could offer greater overall functional efficiency, NBBJ indicated in its predesign summary report.

The new construction is expected to displace several hundred parking spaces. Garwood said temporary spaces would be provided until a comprehensive parking plan for the entire Medical Center is implemented.

STANFORD—

Dr. Stanley N. Cohen of Stanford University School of Medicine has been selected to receive the 1981 Wolf Prize in medicine for his role in discovering and developing recombinant DNA techniques.

Cohen, professor and chairman in Stanford's department of genetics, will share the $100,000 award from the Wolf Foundation of Israel with Dr. Barbara McClintock of the Carnegie Institution of Washington and the Cold Spring Harbor Laboratory.

Cohen was cited by the Foundation for being the first, with his colleagues, to construct a biologically functional hybrid plasmid in 1973, and in the following year to achieve actual expression of a foreign gene implanted in bacteria by recombinant DNA methods.

Through such advances, "Cohen has exercised a central and seminal role in discovering and developing recombinant DNA methodology," the Foundation noted, "and in demonstrating its usefulness for analysing complex genetic elements, and for obtaining expression of foreign genes in bacterial cells."

McClintock was cited for her contributions to the understanding of chromosome structure and function, including her identification and description of transposable genetic elements.

The Wolf Foundation has awarded prizes annually since 1978 "for outstanding contributions on behalf of mankind." The Wolf prizes are sometimes referred to as Israel's equivalent of Sweden's Nobel prizes.

This year's prize-awarding ceremony will take place at the Israeli Knesset in March 1982 when the president of Israel will distribute the awards. The presentation ceremony will coincide with the first anniversary of the death of the founders, Dr. and Mrs. Ricardo Wolf who died in February and March 1981, respectively.

The Wolf prizes, each worth $100,000 to be shared equally in the case of more than one recipient, are announced annually in five fields, including agriculture, mathematics, chemistry, physics and medicine.

Five prize committees consisting of several internationally prominent scientists in each field select the award recipients.

-more-

The purpose of the Wolf Foundation, which began its activities in 1976, is "to promote science in all its fields and art in all its forms." With the consent of the Foundation's trustees, a sixth prize may be awarded for achievements in the sphere of art (music, painting, sculpture, or architecture).

Cohen began investigating gene structure and evolution in the early 1970's with studies of plasmids, circular bits of DNA that exist separately from the primary genetic apparatus of bacterial cells.

In 1972, he and his colleagues at Stanford found that they could change the genetic legacy of bacteria by introducing plasmids into the cells.

With Dr. Herbert Boyer at the University of California, San Francisco, Cohen's group showed that they could make and clone functional "hybrid" plasmids using bits of DNA pieced together from separate *E. coli* plasmids.

The following year Cohen and his colleague Annie Chang reported that genes from an unrelated bacterial species could be stitched into an *E. coli* plasmid and inserted in the *E. coli* cell where the genes propagated and expressed the biological functions they displayed in the original host.

The next step was to try the same thing using animal genes, and this was achieved in 1974 with the report by the scientists that animal genes, introduced by plasmids, were successfully propagated in bacteria. A powerful new technique for genetic transplantation was born.

In 1978, Cohen and his colleagues achieved the first biological expression of genes from mammals which had been transplanted into bacterial cells. This achievement, which has brought closer the ultimate knowledge of the structure and function of genes, also opened the prospects for genetic engineering and "bacterial factories," clones of bacteria that could produce a cheap and unlimited supply of essential antibiotics, vitamins and hormones.

A native of Perth Amboy, New Jersey, Cohen, 46, received his B.S. from Rutgers University in 1956 and his M.D. in 1960 from the University of Pennsylvania School of Medicine.

He came to Stanford in 1968 and currently holds joint appointments in medicine and genetics.

Cohen is a fellow of the American Academy of Arts and Sciences and a member of the National Academy of Sciences. He received the Burroughs-Wellcome Scholar Award in Clinical Pharmacology in 1970, the Josiah Macy Jr. Foundation Faculty Scholar Award in 1975, and was chosen a Guggenheim Foundation Fellow in 1975.

Cohen has also received the V.C. Mattia Lectureship Award in 1977, the Marvin Johnson Award from the American Chemical Society for 1980, and an Albert Lasker Basic Medical Research Award in 1980.

Mailed Wednesday, October 28, 1981.

STANFORD—

Man and mouse have in common more than meets the eye.

Researchers at Stanford University School of Medicine now report that some pieces of the hereditary material, DNA, are nearly identical in mouse and man.

The common chemistry was recently found by scientists analyzing the submicroscopic, fine structure of pieces of DNA from the energy "factory" of the cell, the mitochondrion.

They have now published in the October (Part II) issue of the journal *Cell* the complete sequence of the circular DNA molecule (precisely 16,295 nucleotides long) from mouse cell mitochondria.

Until recently, DNA, a helical double-stranded molecule composed of thousands of nucleotides strung one after another like beads on a string, kept its fine structure a mystery. It seemed a formidable task, even impossible, to discover the identity and sequence of each nucleotide on a thousands-long chain.

But new analysis techniques have helped researchers to begin to determine the precise sequences of short DNA molecules from mammalian cells. Human mitochondrial DNA was completely sequenced earlier this year by a group of British scientists led by Frederick Sanger, whose development of the sequencing techniques earned him a Nobel Prize.

These are among the first DNA molecules in mammalian cells to be so precisely analyzed.

The importance of sequencing DNA molecules, according to Dr. David Clayton, associate professor of pathology and leader of the Stanford research group, is that it will help scientists learn how DNA, the cell's master molecule, directs protein synthesis, controls its own replication, and guides other cell activities.

"It's like having a book in a foreign language and suddenly being presented with a dictionary," Clayton said.

Among the discoveries Clayton's group has already made as a result of the sequencing feat is that the mouse mitochondrial DNA is nearly identical in overall sequence and in gene organization to human mitochondrial DNA, which is 16,569 nucleotides in length.

-more-

The researchers also found that the genetic code in mouse mitochondrial DNA is slightly different from that found in most other DNA strands. (The genetic code is the code cells must decipher when using DNA to to make proteins—triplets of nucleotides specify the amino acids of which proteins are made.)

Because these changes in the standard genetic code have also been found in human and cow mitochondrial DNA, they may be a common feature of mitochondrial systems in mammals, Clayton suggests.

Clayton's colleagues on the sequencing project were Maureen Bibb, Richard Van Etten, Catharine Wright, and Mark Walberg.

Sequencing of the mitochondrial DNA has also permitted the researchers to complete a transcription "map" of the molecule—this means that they have identified portions of the DNA that code for proteins and other biologically important molecules. Sites on the DNA molecule that control the DNA's own replication process are also now located and under study, Clayton says.

One of the most useful aspects of knowing the entire sequence of this DNA molecule, says Clayton, is that researchers can now alter the molecule by site-specific mutagenesis in an effort to learn more about how DNA molecules work. "This is a powerful approach in which we make a change at a specific point on the genome, and try to put it back in the cell and study the results," Clayton explains. This type of detailed study of mouse mitochondrial DNA is likely to reveal some clues about how DNA molecules direct the scope of cell activities, Clayton says.

The research was supported by grants from the National Institutes of Health and from the American Cancer Society.

STANFORD—

In keeping with a commitment of service to the community, Stanford has scheduled its first Medical Center career symposium for Saturday, Nov. 7, from 10 a.m. till 2 p.m., in the Fairchild Auditorium and Lobby.

Intended as an introduction to both Medical School and Hospital departments, the event will include tours of the Center, an 11 a.m. lecture by Stanford psychiatrist C. Barr Taylor on job stress, and an offering of informational brochures, maps, and selected publications.

Departmental representatives will be on hand to discuss the various types of positions in their areas, current openings, and the general functioning and focus of their departments.

The event is also intended to boost recruitment efforts for experienced clerical and administrative staff.

Gail Selke, employment coordinator in the Medical School's Human Resources Group, and Renee Wald, coordinator of employment/recruitment in the Hospital, are responsible for planning the program—which is the first in what may become a series of annual or semi-annual events.

Since each department has had to do its own recruitment, says Selke, hiring has been difficult—particularly in support positions where competition from industry is high.

"We hope to attract people with medical backgrounds, who understand the terminology, for example."

However, Selke emphasizes, the symposium is not expected to cause much hiring immediately, but rather to expose potential applicants to current and future job possibilities at the Medical Center.

Career Symposium I is free and open to the public. Refreshments will be served.

For further information about the activities planned, call Selke, at 497-6295, or Wald, at 497-6361.

STANFORD—

Art galleries aren't the only place to exhibit one's paintings.

As members of the Palo Alto Art Club have discovered, hospital corridors do very nicely too.

As a result, in exchange for providing a showcase, Stanford University Hospital since 1966 has been treated to a wide assortment of oils and watercolors adorning its otherwise naked walls.

Frances Tuban, a 76-year-old life member of the Club, was one of the first to exhibit her work at Stanford. "Now I'm not so concerned with selling, but I still paint. You don't have to retire from art," she says with pride, having recently undergone open heart surgery.

And having been a patient herself at El Camino Hospital, Tuban knows what a difference pleasant surroundings can make. "I'd love to look at the pictures on the wall while I was in the hospital," she says. "Even when you're being pushed down to X-ray, it's nice to see artwork."

Adds Carolyn Hofstetter, a life member who teaches oil painting, "I don't think people realize how many hospital patients are ambulatory and can enjoy the paintings. They're not just for visitors and employees, but patients too."

The paintings are hung in groups for periods of three months at a time. While on exhibit, they are also on sale, with a list of prices retained by Hospital Administration. The proceeds from all sales are split: 70 percent goes to the artist, and 30 percent to the Club.

"This is a better deal for artists than in most galleries," says Hofstetter, with the Club since 1961, pointing out one advantage available to members.

Each painting is secured to the wall by a padlock, onto a security hook. Since neither the Art Club nor the Hospital has insurance coverage for the paintings, none over $300 as the selling price are displayed.

-more-

The Art Club, whose headquarters are now located at 668 Ramona Street in Palo Alto (phone: 321-3891), was founded in 1921. Today's membership, totaling over 800, is drawn mainly from San Francisco to Monterey, and is open to amateur and professional artists and those wishing to help promote interest in the fine arts. A non-profit organization, the Palo Alto Art Club is the second largest art club in the nation.

A 60th anniversary celebration is currently underway at the Club, while its Spanish-style building downtown undergoes repainting and remodeling. This fall a major fund raising effort begins in order to support the renovation.

"Some of us are worried about the word 'club,' " says Hofstetter, "because it sounds like it's for members only. But it's really more of a school, entirely open to the public."

The Club offers a variety of classes, taught by a teaching staff of prominent artists, in all painting mediums, Chinese brush painting, drawing, life drawing, collage, portrait sketching and painting, stained glass, calligraphy, printmaking, etching, lithography, sculpture, and more. A scholarship fund helps needy children and senior citizens participate in the classes offered.

"There are evening classes too," says Hofstetter, explaining that members pay slightly lower class fees than others.

They also have the privilege of exhibiting in the Club's sales and rental gallery, and in outside shows at SUH, Hoover Pavilion, libraries, the Surgical Center of the Palo Alto Clinic, and other community service locations. Annual shopping center and art fair exhibits provide members with additional sales and exhibiting opportunities.

Says Hofstetter, "I think the Art Club does a lot for the community and can do more."

At Stanford, administrative services manager Marjorie Hildahl agrees. "We appreciate the Art Club's assistance in beautifying the Hospital's corridors," she says. "We look forward to continuing the good relationship we've always enjoyed."

TWO STORIES: Lisa Ames, Laura Hofstadter (415) 497-6911

STANFORD—

Dr. Saul A. Rosenberg, professor of medicine and radiology in Stanford's School of Medicine, is among the fifty new members recently elected to the Institute of Medicine for five-year terms beginning Jan. 1.

New members are elected by present active members from among candidates chosen for major contributions to health and medicine, or to such related fields as the social and behavioral sciences, law, administration, and engineering.

Rosenberg has been at Stanford since he first joined the faculty here in 1961. He has been chief of the Division of Oncology since 1965.

—30—

STANFORD—

How do oral contraceptives and physical exercise interact to control blood cholesterol levels in women?

This question may soon be answered by research under way at the Stanford Heart Disease Prevention Program.

The researchers are seeking women volunteers between the ages of 21 and 35 in the following categories to participate in the study:

- using oral contraceptives and physically active;
- using oral contraceptives, with a sedentary occupation and no regular physical exercise;
- not using oral contraceptives, with a sedentary occupation and no regular physical exercise.

Volunteers will make one visit to the Heart Disease Prevention Program facilities at 730 Welch Road. The staff will draw small blood samples, conduct a bicycle fitness test, and determine body density by underwater weighing.

Participants will receive detailed information on their blood cholesterol levels, percentage of body fat, and their maximum oxygen transport capability (a measure of physical fitness).

Those interested in volunteering should call Dan Merians, at (415) 497-6254, for more information.

EDITORS: ADVANCE FOR RELEASE AFTER 5:30 P.M. PDT FRIDAY OCTOBER 23 TO COINCIDE WITH PRESENTATION OF RESULTS AT THE INTERFERON CONGRESS IN SAN FRANCISCO.

STANFORD—

Interferon produced by recombinant DNA techniques seems to be passing its early safety tests, Stanford University researchers reported Friday October 23 in San Francisco.

This means that sufficient quantitities of the highly purified protein may soon be available for definitive clinical studies on the substance's anti-cancer and anti-viral potential.

Preliminary clinical trials at Stanford University Medical Center using interferon made by genetically engineered bacteria indicate that the gene-splicing product does not differ significantly in function from interferon derived naturally from human cells.

Because the bacteria-produced substance is 98 percent pure, doctors can now be sure that any effects observed are due to interferon itself and not from other components present in the cruder preparations previously available which were only about 2 percent interferon.

These early trials have also produced tentative but encouraging results about the biosynthetic protein's anti-tumor effects, Stanford doctors report.

Four of eight patients with advanced cancers of various types who received intramuscular injections of interferon over a period of 34 to 56 days demonstrated some evidence of tumor regression, according to Dr. Sandra Horning, clinical instructor at Stanford University School of Medicine.

However, Horning stressed the preliminary nature of the study, which was not the standard "randomized double-blind" experiment used to test drug effectiveness but was rather a "phase I" safety study designed to test only how well patients tolerated various doses of this new synthetic form of interferon.

"The fact that both preparations have similar effects in patients indicates to us that it is the interferon and not an impurity or other factor responsible for the effect we're looking at," Horning said.

Horning presented the results of the phase I study Friday October 23 at the second annual International Congress for Interferon Research in San Francisco. Her colleagues on the study were Drs. Jedd Levine, Richard Miller, Saul Rosenberg and Thomas Merigan of Stanford.

The recombinant DNA-produced interferon, made by inserting the interferon gene from human leukocytes (a type of white blood cell) into bacteria, is manufactured by the pharmaceutical firm Hoffmann-LaRoche, Inc..

-more-

In addition to the eight patients administered the synthetic interferon at Stanford, eight patients at M.D. Anderson Hospital and Tumor Institute in Houston received the drug. These 16 patients were the first to receive bacterial produced interferon, Horning said.

The phase I study was designed to determine toxicity, pharmacokinetics and tolerable doses of the substance rather than its clinical effectiveness in fighting cancer, Horning explained. However, anti-tumor activity was observed in one patient with breast cancer, one patient with chronic myelogenous leukemia, and in two patients with nodular lymphoma.

The Stanford researchers now plan to begin additional clinical testing of the bacterially produced interferon to assess its effectiveness in treating cancer patients while continuing to monitor possible side effects. They are looking for cancer patients to participate as volunteers in the trial, particularly patients with nodular lymphoma. Interested individuals should contact Michelle Meyers at (415) 497-5877.

The major side effects experienced by patients receiving either genetically engineered or natural interferon are fever, fatigue, muscular pain and headache, Horning reported. All of these symptoms are reversible, she added.

Recently interferon has been acclaimed as a miracle drug that can cure every disease from the common cold to cancer. Such claims are wildly exaggerated, Horning said.

The importance of having a plentiful supply of pure interferon is that adequate clinical tests can now be carried out, she noted.

Not only is the bacteria-produced interferon expected to be more plentiful and purer than the cruder blood cell-derived substance—it will also be about ten times cheaper, a boon to researchers who would like large quantities of the material for testing.

Since interferon was first discovered, scientists have learned that there are at least 15 different forms of the protein made in the body by different cell types. In addition to leukocyte interferons, the body produces forms known as fibroblast interferon and immune interferon.

Interferon's natural function in the body is to participate in fighting viral infections and tumors. Interferon administered in fairly large doses has a general anti-growth effect on cells, Horning said.

Other institutions that will study the cancer fighting potential of the biosynthetic interferon in collaboration with Stanford are M.D. Anderson Tumor Institute and the University of Wisconsin.

FOR IMMEDIATE RELEASE

STANFORD—

So far, bioengineering has been mostly "bio" and not much "engineering," says Prof. Channing Robertson, head of Stanford's Department of Chemical Engineering.

Working closely with Stanford administrators over the past two and a half years, Robertson has played a central role in trying to redress this balance, achieve technology transfer and secure more private funding for basic research by universities in this field.

His efforts, and those of many others, culminated in the recent formation of a new, non-profit Center for Biotechnology Research to fund basic academic research and a for-profit firm, Engenics, committed to developing large-scale chemical processing using biologic intermediaries.

Six companies have provided $7.5 million for four years of applied research and development by Engenics. They are: Bendix, General Foods, Koppers, Mead, MacLaren Power and Paper (a subsidiary of Noranda Mines) and Elf Technologies of Societe Nationale Elf Aquitaine.

They also have provided $2.4 million for the non-profit Center for Biotechnology Research, which will fund basic research at Stanford, Berkeley, and other academic institutions.

Governed by three independent trustees, the Center holds a 30 percent share of Engenics. If Engenics proves a commercially important biotechnical enterprise, this share will increase in value, providing universities more private support for fundamental research.

The Center's initial grants include approximately $1 million each to Stanford and Berkeley for four years. Robertson and Dr. Abdul Matin of the Stanford Department of Medical Microbiology will be coprincipal investigators at the University, while Prof. Harvey Blanch of the UC-Berkeley Department of Chemical Engineering serves in a similar capacity there.

Efforts already have started to assemble a 25-member research team, including about two research technicians, two post doctoral fellows, three Ph.D. candidates, and three or more undergraduates at each institution. Trans-Bay meetings are planned monthly.

Stanford President Donald Kennedy says that "while there is no commitment by the Center to support research at Stanford beyond the present contract, I believe this novel approach to the funding of research and technology can set a new pattern of long-term support for university research which can contribute significantly to meeting future needs.

"I am particularly grateful for the far-sightedness of the six companies for developing this new and imaginative approach."

Robertson expects that the non-profit Center will fund at least one proposal from another academic institution this year. Center trustees, who will make decisions about research funding after peer review of proposals, are James E. Gaither, chairman, a partner in the San Francisco law firm of Cooley, Godward, Castro, Huddleson and Tatum; Paul M. Cook, president and chief executive officer of the Raychem Corporation; and Charles J. Hitch, former president of the University of California and former economist and assistant secretary and controller of the U.S. Department of Defense.

The non-profit Center will receive royalty-bearing licenses from the universities under all patents resulting from research it sponsors in accord with the standard policies of each university. In addition, the Center expects to receive licenses from Stanford under some of the basic patents covering biotechnology and genetic engineering on the same terms as others.

Engenics' basic purpose differs significantly from that of many other highly publicized firms. It seeks to develop reliable, cost effective biotechnological processes, rather than genetically altered microorganisms with the capability of synthesizing specific products.

-more-

 The company will be based in the Bay Area, though no site has yet been chosen. "Within the next 10 years, biotechnical processes will be developed and refined to the point where living cells will produce, from inexpensive raw materials, a broad spectrum of chemical products in the areas of pharmaceuticals, food stuffs, agricultural chemicals, industrial chemical intermediates, and gaseous and liquid fuels," a prospectus notes.

Engenics will establish a laboratory to develop specific processes to the point where useful products can be commercially manufactured and separated in continuously operating systems.

Robertson and Blanch will be consultants to the new company and are among its founders. The 30 percent of Engenics stock held by the non-profit Center covers most of the usual "founder's share" of stock in a new company.

Other founders of the company are William Eberle, corporate director, former Stanford trustee, and former special representative of President Ford for trade negotiations; Maurice Lazarus, chairman of the finance committee of Federated Department Stores, a Harvard overseer, and a director of Massachusetts General Hospital; and Franklin Lindsay, former president and chairman of Itek Corporation.

Lindsay serves as Engenics board chairman, with Blanch, Eberle, and Lazarus as directors. Other directors include one executive from each of the six firms providing the initial capital and the chief executive officer of Engenics. The companies retain a 30 percent share of the firm, with the rest held in reserve as incentives for the new firm's personnel, who are in the process of being selected.

Robertson sees genetic engineering as a major design tool in the development of reactor systems of the future, based on renewable bioresources rather than on fossil fuel hydrocarbons.

His interest stems from work done with Prof. Alan S. Michaels and Larry Waterland, a Ph.D. candidate in chemical engineering, in 1973.

"The aim of our project was to immobilize an enzyme, much as we immobilize other catalytic materials. Enzymes are nature's catalyst," Robertson says.

To immobilize enzymes, the Stanford group used synthetic hollow fiber "bioreactors."

"Essentially, these were analogs of conventional, tubular catalytic wall reactors commonly used in the chemical process industry," Robertson explains. "To picture what these are like, just imagine a tube. The enzyme, which is a protein, is placed in the wall of the tube. Under magnification, the wall looks like a household sponge; it's extremely porous and full of holes. The enzyme fits into these holes and remains there.

"Material to be converted into a product is passed through the interior of the tube, diffusing out into the sponge-like wall. This brings it in contact with the enzyme, which converts it into the product.

"The enzyme is fixed and immobilized in space. The reactant is brought to it and the product is continuously removed. Our view at that time was that we had demonstrated a new and generic approach to enzyme immobilization and biological reactor design."

Soon afterwards, while on a sabbatical in Switzerland, Robertson reflected on this work and its possible application in genetic engineering. One of the key problems, as he saw it, was taking the fruits of genetic engineering and microbiology and getting them into large scale production, particularly where the resulting products—unlike drugs—did not have a very high added value.

"For that to happen, ways would have to be devised to take microorganisms or cells which may or may not have had genetic alteration and place them in an environment—in a reactor—where they could perform their functions for extended periods of time.

"The translation of a cell or microorganism from the bottom of the molecular biologist's test tube into a fully operational bioreactor could be a step as major as the actual genetic engineering itself.

"What occurred to me is that a cell is nothing more than a vast collection of enzymes, or chemical catalysts. From an engineer's viewpoint, one should be able to immobilize them much as we had done with individual enzymes in the early 1970's. -more-

 "With genetic engineering available to us, it would be possible to tailor the cellular biochemistry in such a way that we could circumvent some of the idiosyncracies of nature and produce catalytic systems which would be optimal for a given process.

"One other rather interesting aspect of cells and most microorganisms is that they operate at room temperature and room pressure. Therefore, in principle, we have an enormously reduced energy load relative to common chemical processing (catalysis) which is most often done at elevated temperatures—many hundreds of degrees Centigrade—and usually under extreme pressure conditions.

"Since practically every chemical that one can imagine, or at least every precursor chemical, can in fact be produced by a cell—whether it is an animal cell, a plant cell, or a bacterial cell—you have before you all of nature to select from.

"At that point, one can ask the genetic engineer to fine tune that cell. Then if we, as engineers, provide the hardware to put that cell into place so that it may perform its biochemical functions in the most optimal manner, out of this would emerge an entirely new chemical processing industry.

"In the next decade or two, this could have a major impact on the fossil-based hydrocarbon chemistry now in place. It would offer the possibility of *in situ* catalysis regeneration, because cells grow and divide. Platinum doesn't. Cells renew themselves."

One area in which practical applications could emerge is foods. "One can produce a variety of amino acids—food supplements, vitamins, food texturizers, proteins, flavors, fragrances, colors—all of which would be natural products," Robertson notes.

In his own laboratory, William Smith, a Ph.D. graduate student, was working on aspartic acid, one half of a coupled molecule known as aspartame, recently approved by the Food and Drug Administration as a sweetening agent.

"When we began 12 months ago, we selected aspartic acid simply because it was there," Robertson says. "Quickly, but quite by chance, a great deal of interest was expressed in our work."

The applications of scaled up genetic engineering processes will most likely first occur with the production of pharmaceuticals, he noted. But the same may prove true in time with fuels and forest products.

"My view is that the hydrocarbon feed stocks that we use now—coal, oil, and gas—will be slowly replaced—or at least supplemented—by biomass feed stocks," Robertson says. "Forest products and agricultural materials will play a major role in supplying biomass material to chemical plants of the future. These raw materials, essentially glucose or sugar, will be converted into other chemicals, some of which might be fuel precursors or fuels themselves.

"Biological sensors may be used for instrumentation. Biologically based processes may be used to concentrate metals, to remove waste from waters, or for countless other tasks."

The impact could be just as broad as the development of microprocessors in electronics, Robertson believes.

In electronics, rapid advances in hardware were not proliferated in a host of public uses until software programmers realized the potential of small chips. "What's happened in genetic engineering is just the reverse," he notes.

"The software programmers came first. They've been able to go in and alter the genetic code and rewrite the programs, but they have no hardware to put them into."

When he returned from his sabbatical, Robertson went back to his lab, joined forces with Profs. Michaels and Stanley N. Cohen at the Medical School, "and took what we knew how to do best—which was put enzymes into hollow fibers—and instead put in whole cells."

Working closely with Michaels, Cohen, Smith and two other Ph.D. students, Douglas Inloes and Shari Libiki, "we found we could achieve cellular densities which were absolutely astounding—tens of thousands of times higher than any conventional fermentation process available," Robertson says. -more-

"Now we're spending a great deal of time trying to understand the behavior of cells which are essentially packed in such a way as to mimic our (human) bodies, in the way capiliaries perfuse our tissues."

Robertson gave a talk describing his work to a University seminar at Stanford in 1978. Lindsay, a participant, was fascinated. Board chairman of Itek and a long-time friend of Stanford, he later came to Robertson's office to see if there were appropriate ways in which the transfer of technology from campus to the public could be accelerated, with major benefits being returned to the University.

"I feel very, very strongly that any of the work that I do could not have happened had I not been at Stanford," Robertson says. "It's that environment that permits my colleagues and me to unleash our creative spirits and put them to work. And for that, Stanford should be a beneficiary of whatever it is that I do."

Eberle, then a Stanford trustee, and Lazarus of Harvard were among those joining in a long series of discussions. At one point, more than two years ago, an industrially sponsored consortium to support basic research in several fields at the University was considered. But it failed to materialize.

After the name Engenics was coined, an effort was made to organize an off-campus firm with no University ties with a combination of venture capital and corporate support, with Michaels as president. This, too, fell through. Michaels decided he would no longer play any major role in subsequent organizational efforts. But the company name was retained, leading to some confusion in subsequent press reports.

Blanch and Robertson turned back to their respective universities. After Lindsay and others helped draft the basic framework, Robertson contacted Gerald Lieberman, Stanford's vice provost and dean of graduate studies and research, who kept President Kennedy posted.

"We wanted to do everything in a way that was open, where the University could question, challenge, or make suggestions," Robertson says. "If at any point my involvement compromised their view of me as a member of the academic community, I asked them to let me know, so things could either be changed or brought to an end.

"I didn't want to put anyone in an awkward light."

He praised the administration for a "very supportive" attitude. Several offices—legal, sponsored projects, technology licensing"—commented on various proposals. The final version took shape in late February and early March this year.

"The hard decision was that I would not have anything major to do with Engenics. People asked me if I was going to be president. My students thought I was going to be president; some of the faculty thought I was going to leave. Others thought I was on the board of directors. But I'm none of those.

"Having put the agreements for the company and the Center into place, I can sit and watch them grow, and see the results of fundamental research put to work. As an engineer, it's satisfying to see that happen.

"What we have right now is an embryo of what could potentially be a major component of all the funding that's available for biotechnology.

"There are hundreds of similar type companies that could conceivably participate in similar sorts of arrangements in other universities.

"Each of us has funding from other sources besides the Center for Biotechnology Research. For instance, I have funding from Monsanto in my laboratory in the same area. Funds from the Center now allow us to expand an activity that's already in place, for which we are very grateful.

"As with any form of sponsored research, any other corporation or any other government agency may participate in the funding of research in either Blanch's laboratory or my laboratory.

What if another company, not among the sponsors of Engenics and the Center, wants to find out more about this research?

-more-

"They'll have the same access, coming and talking with me, listening to seminars, as they normally would under any other circumstances," Robertson replies.

Then what's the advantage to the sponsoring companies?

"They obtain a 'window' on the new technology; that's the primary advantage," he continues. "They hold equity in Engenics. In the end, what Engenics does probably will bear little relationship to what I, as a single investigator, do in my laboratory.

"In principle, it could, but if Engenics sits and waits for me to discover something, the chances it will be successful are highly unlikely.

"My feeling is that the work we do is of such a basic and fundamental nature that its expression—what will be done with it in an applied sense—is as big a jump as the jump we took to create that basic science in the first place.

What's the difference to society?

"My view is that the more people who are thinking about the applications of this research, and the more groups that are working on it, the greater the chances are that the public ultimately will benefit," Roberston says.

"There's practically no way to know in advance precisely how or where the breakthroughs will come.

"That's why it's important to keep communications open across many different channels—in the lab, out to industry, and among academics who share our research interests."

Does the source of support make any difference in your daily research activity?

"No. I'm not compartmentalizing my lab, my students, my research or my thoughts. When that becomes the dominant concern, the research is in serious jeopardy."

What about other ways of commercializing the results of basic research?

"It's still relatively easy for professors to move off campus and take a major stake in private firms designed to develop their laboratory discoveries. I could have done so with Engenics," Robertson notes.

"But that can blur the distinctions between basic science and its applications. Moreover, it does not relieve the growing financial pressure on university research.

"It's vital to find ways of increasing the funding of basic science nationally, especially when large cutbacks appear likely for NSF, NIH, and other federal sources.

"The consequences of such reductions could be especially serious for graduate students and young professors who have not had time to establish their reputation.

"To the extent that the Center for Biotechnology Research and other efforts to increase private funding are successful, the impact of federal cuts may be diminished somewhat.

"The point is to strike out and try something new, and see if it works. And if it does, it will get modified, changed, and improved.

"The real measure of what we do, and whether or not it's acceptable in terms of University and academic standards, is peer review and whether or not it can be published.

"We're not barred in any way from publishing our work. The standards by which our work is measured are the same as they've always been, and we intend to meet those standards."

In the last national evaluation by department heads, Stanford's work in chemical engineering was ranked the best in the U.S.

EDITORS: ADVANCE FOR RELEASE NO EARLIER THAN 6:30 P.M. EDT WEDNESDAY OCTOBER 21 TO COINCIDE WITH NEWS EMBARGO SET BY THE *NEW ENGLAND JOURNAL OF MEDICINE.*

STANFORD—

Rheumatoid arthritis patients who were formerly wheelchair-bound have become active and obtained relief from pain following treatment with a type of radiation therapy developed by Stanford University doctors.

Nine of eleven patients with intractable rheumatoid arthritis who were treated with total lymphoid irradiation (TLI) regained considerable function as symptoms of morning stiffness, joint tenderness and joint swelling substantially diminished, according to a report by Stanford researchers in the October 22 issue of the *New England Journal of Medicine.*

Maximum improvement occurred six months following the six-week treatment period, said Dr. Samuel Strober, associate professor of medicine and chief of immunology at Stanford University School of Medicine. And these benefits have continued for up to 18 months with few side effects following the radiation dose, he added.

However, this is a pilot study and additional clinical testing of TLI for advanced rheumatoid arthritis is needed before its usefulness is proved, Strober cautioned.

His associates in the study were Stanford researchers Dr.Brian Kotzin (now at the University of Colorado Health Sciences Center), Dr. Edgar Engleman, Dr. Andrei Calin, Dr. Richard Hoppe, Geoffrey Kansas, Candace Terrell, and Dr. Henry S. Kaplan.

Their work was supported in part by grants from the National Institutes of Health and the Howard Hughes Medical Institute.

In the nine patients showing marked improvement, TLI brought about an 82 percent reduction in morning stiffness, 74 percent reduction in joint tenderness and 70 percent decrease in joint swelling, Strober and his colleagues reported.

The significance of these results, he said, is that an advanced arthritis patient's lifestyle could be transformed from that of a wheelchair-bound person to one in which the patient could resume many normal daily activities with a maintenance drug regimen of only aspirin.

Furthermore, the doses of TLI administered (a total of 2,000 rads) are low enough that temporary side effects such as nausea, loss of appetite and fatigue, are limited while long-term hazards, such as development of cancer, are remote, Strober said.

Because of its relatively benign side effects, if proven effective in further testing TLI treatment would be preferable to the powerful cytotoxic (cell-killing) drugs rheumatoid arthritis patients are currently given when they have failed to improve with milder agents (such as anti-inflammatory drugs, gold compounds and penicillamine).

-more-

TLI is a form of treatment in which radiation from a linear accelerator is targeted on lymph nodes throughout the body.

It was developed over two decades ago by Dr. Henry S. Kaplan, D'Ambrogio professor of radiology at Stanford, and it has for years been the treatment of choice for many patients with Hodgkin's disease, a cancer of the lymphatic system, Strober explained.

During the radiation treatment, non-lymphoid tissues in the body are shielded by lead barriers and the radiation is focused on lymph nodes of the neck, chest and abdomen, thymus gland, and spleen.

TLI has helped improve the cure rate of early stage Hodgkin's disease from only 30 percent in the 1960's to 86 percent today.

TLI causes a profound and prolonged drop in the lymphocytes, white blood cells responsible for the body's immune responses, including the defenese against infection. Yet, less than one percent of the Hodgkin's patients treated with TLI contract severe bacteriological infections requiring hospitalization.

In addition, none of the several hundred patients treated with high dose radiation in this manner over the past 10 years has developed leukemia, Strober said.

Afflicting nearly two million people in the United States, rheumatoid arthritis is a disabling disease in which the body's immune system is thought to attack its own tissues causing severe pain and inflammation in joints and muscles.

It is one of several "autoimmune" diseases and doctors suspect it may be caused by an abnormality of one type of white blood cell (a "suppressor" lymphocyte) which normally keeps the immune system in a delicate balance.

Suppressor cells are like the brakes of the immune system; without their inhibiting action a "runaway" effect can take place in which the defense system's destructive cells attack everything nearby.

TLI, which causes a long-lasting drop in the overall number of lymphocytes, actually increases the relative proportion of suppressor cells, Strober and his colleagues discovered. This may account for its ability to counteract rheumatoid arthritis, Strober suggested.

"This form of radiotherapy deserves further study," concluded Strober and his colleagues, who have already initiated a larger controlled clinical study of TLI in rheumatoid arthritis patients.

STANFORD—

A radiation treatment commonly administered to patients with cancer of the lymphatic system is now showing promise of controlling tissue rejection in kidney transplant patients.

The technique is total lymphoid irradiation (TLI), a form of radiation treatment selectively administered to the lymphoid tissues which control the body's immune system.

In early clinical testing, it has been effective enough that three kidney transplant patients receiving the treatment are overcoming the body's tendency to reject the foreign organ with dramatic reductions in the usual doses of anti-rejection steroid medications.

Dr. Samuel Strober, associate professor of medicine and chief of immunology at Stanford University School of Medicine, presented these preliminary but encouraging results at a public scientific symposium held Saturday October 17 at the Medical School's Fairchild Auditorium. The symposium, "Perspectives on Blood Related Science in the 1980's: New Dimensions in Medical Care," is one of several events celebrating the formal opening of Stanford Medical School's new Blood Center. The speakers discussed a variety of blood-related medical discoveries that are beginning to have a broad impact on patient care.

Strober, who is collaborating with members of the renal transplantation teams at the University of California, San Francisco and at Pacific Medical Center, said TLI needs considerably more clinical testing before its usefulness at preventing rejection in transplant patients is proved.

Alternatives to conventional immunosuppressive drugs (such as steroids and azathioprine) are needed, Strober explained, because of these agents' undesirable side effects, among the most serious of which are suppression of all parts of the patient's immune system which leaves him highly susceptible to infection, and an increased risk of certain types of cancer after several years of therapy.

TLI is not new. It was developed over two decades ago by Dr. Henry S. Kaplan, Stanford professor of radiology, and it is "the treatment of choice" for many patients with Hodgkin's disease, a cancer of the lymphatic system, Strober explained.

During the radiation treatment, which is usually done on an outpatient basis, non-lymphoid tissues in the body are shielded by carefully placed lead barriers and the radiation is focused only on the cancerous cells in the lymph nodes.

The potential application of TLI to controlling rejection in transplant patients came about after Strober, Kaplan and colleagues noticed that Hodgkin's patients treated with TLI have a highly suppressed immune system (similar to that of patients receiving steroid medications to prevent rejection).

The TLI temporarily reduced to a very low level the number of lymphocytes in the Hodgkin's patient's body. It also brought about a more permanent alteration in the balance of different classes of lymphocytes. Lymphocytes are white blood cells that participate in the immune reaction that protects the body from bacteria and other infectious and toxic agents.

Yet, unlike patients on steroids who are highly susceptible to infection, Hodgkin's patients who have been treated with TLI have a very low incidence of infection.

Further study revealed that whereas steroids and azathioprine are nonselective in suppressing the immune system, TLI actually changes the balance among various components of the immune system, enhancing the population of "suppressor" lymphocyte cells.

-more-

Suppressor cells are like the brakes of the immune system. They slow an all-out attack on foreign agents and thus, in transplant patients, inhibit the body's efforts to reject the foreign tissue.

One of the kidney transplant patients who received TLI for six weeks prior to the transplant has now survived nine months, Strober said, and has received no steroid medications since 55 days following his operation, a 95 percent reduction in the usual post-transplant steroid dose.

In another symposium presentation, Dr. Thomas Merigan, professor of medicine and chief of infectious diseases at Stanford, described the potential clinical uses for interferon, a natural protein obtained from white blood cells.

Merigan reported that early studies of interferon manufactured through gene-splicing techniques indicate that the biosynthetic substance is very similar to teh naturally derived product.

This means that sufficient quantities of the highly purified protein may soon be available for definitive clinical studies on the substance's anti-cancer and anti-viral potential.

Dr. Bruce Reitz, assistant professor of cardiovascular surgery, outlined the clinical experience in the new heart/lung transplantation program at Stanford Medical Center. The program relies heavily on expertise provided by the Stanford Blood Center in matching donor and recipient, screening blood for the highly immunosuppressed transplant recipients, and in providing specialized blood components.

Other symposium speakers included Dr. Edgar Engleman, assistant professor of pathology and medical director of the Blood Center, who discussed "Monoclonal antibodies: new weapons in the diagnosis and treatment of human diseases;" Dr. Rose O. Payne, professor of medicine emeritus and director of the tissue typing laboratory at Stanford University Hospital, who talked about "HLA and clinical applications;" and Dr. F. Carl Grumet, associate professor of pathology and director of the transfusion service at Stanford University Hospital, whose talk covered "Cytomegalovirus infection in transfusion recipients: avoidance by blood screening."

Dr. David Korn, professor and chairman, department of pathology, who moderated the program, noted that all of the blood-related research topics presented by the speakers would most likely have "an impact in patient care in less than 10 years."

Korn added that nearly all blood-related research programs can be carried out with the very small samples that are drawn separately to be used for screening blood from volunteers before their blood is given to patients. Therefore "most blood goes toward patient care," he said, adding that "one unit goes a long way."

In welcoming symposium participants, Dr. Lawrence G. Crowley, vice president for medical affairs, said that the purpose of creating the Stanford University Medical School Blood Center was "to bring together in one place and as close to the Medical Center as possible a critical mass of physical resources as well as intellectual and other human resources, that will allow for provision of high quality patient care services, and at the same time to provide a stimulating environment for exciting research and teaching in blood-related sciences."

The symposium was the second in a week-long series of events to celebrate the formal opening of the Blood Center which is located at 800 Welch Road in Palo Alto, adjacent to the Medical Center.

On Tuesday October 20 Buddy Hatton will host a live KSFO broadcast from the new Center. On Wednesday October 21, the Center will be open with special refreshments for blood donors courtesy of Swensons, McDonalds and Haagen Dazs. On Thursday October 22 special guests at the Blood Center will be members of the Stanford Football Team, Stanford Band and the Stanford Dollies.

STANFORD—

"The Science of Birth" will be the focus of this fall's Progress in Medicine lectures series, a community outreach program sponsored by the Stanford University Medical Center.

In an effort to foster public understanding, Stanford faculty physicians will discuss both the evolving new science of birth and the focus of modern obstetrics: to determine health and disease while the fetus is still in the womb and treat accordingly before birth.

The autumn quarter will open Oct. 28 with an introductory presentation by Dr. W. LeRoy Heinrichs, professor and chairman of the Department of Gynecology and Obstetrics. Also speaking will be Dr. Kent Ueland, professor of gynecology and obstetrics and chief of the section of maternal/fetal medicine, and Dr. David Stevenson, assistant professor of pediatrics and associate director of the Nurseries.

They will discuss "The Regionalization of Perinatal Services," an education and outreach program designed to improve the outcome of high risk pregnancies throughout the Central Coast Region of California through newly established applications of maternal/fetal medicine.

On Nov. 4, Dr. Paul A. Hensleigh, associate professor of gynecology and obstetrics, will talk about "Being Born Healthy," and the risks and benefits of predicting birth defects.

Dr. P. Herbert Leiderman, professor of psychiatry, will discuss "Mother to Infant Social Bonding," Nov. 11. His focus will be the effects of early contact on maternal attitudes and behavior.

The Progress in Medicine lectures were initiated at Stanford in 1966 by Dr. Joshua Lederberg, then professor and chairman of the Department of Genetics, to provide an opportunity for leaders in academic medicine to share their insights and perspectives with the community.

Lederberg had observed: "The community has little opportunity to be informed of the exciting developments in medicine. Public understanding of these developments is of the utmost importance to social decisions."

This year the series will focus on a single theme—the development of the child—for the entire season, of which the Science of Birth is only Part 1. The winter and spring quarter programs will be announced later on.

All autum quarter presentations will take place in the Medical Center's Sherman Fairchild Auditorium, at 7:30 p.m. Admission is free, and seating is limited. There are no reserved seats, and no tickets will be issued. Early arrival is recommended to permit the best choice of parking and seats.

For further information and registration forms, call the Medical Center's Office of Public Events, at 497-6389.

STANFORD—

Stressing a dual role of patient care and scientific innovation, Stanford University President Donald Kennedy formally opened the new Blood Center in ceremonies Friday (Oct. 16).

"By being a center for new developments in this area—a capacity we make possible through this new addition (of a Blood Center)—we can also contribute to the care of generations to follow, in this community and in others," Kennedy said in remarks prepared for delivery to a group attending the afternoon ceremonies.

A major feature of the opening program is a scientific symposium open to the public scheduled Saturday (Oct. 17) from 9 a.m. to noon in Fairchild Auditorium.

The new facility includes a donor center and processing facilities. Donor recruiter Maureen Roskoph said all of the blood is used for patients in the community, unless the donor is informed in advance that his blood is needed for research.

Specialized equipment, including an irradiator, is available to prepare blood for heart transplant patients, as well as for all hospital emergency and general medical needs.

In addition to Kennedy, welcoming remarks at the opening were to be given by Palo Alto Mayor Alan Henderson; Lawrence G. Crowley, Stanford's vice president for medical affairs; R. Hewlett Lee, chief of surgery at Palo Alto Medical Foundation, and Melvin C. Britton, 1980-81 president of the Santa Clara County Medical Society.

The scientific symposium, entitled *Perspectives on Blood Related Science in the 1980s: New Dimensions in Medical Care*, was to feature six Stanford scientists.

Pioneer transplant surgeon Dr. Bruce A. Reitz was to discuss *Heart and Lung Transplantation: A Review*. Dr. Thomas C. Merigan, professor of medicine was to lecture on *Interferon: A Useful Product of White Blood Cells*, while Dr. Edgar G. Engleman, assistant professor of pathology and medicine, as well as director of the blood center, chose the topic: *Monoclonal Antibodies: New Weapons in the Diagnosis and Treatment of Human Diseases*.

Other speakers are F. Carl Grumet, associate professor of pathology and director of the hospital transfusion service, who was to discuss the screening out of infections in transfusions. Rose O. Payne, professor of medicine emeritus and director of the tissue typing laboratory was slated to speak on *HLA and Clinical Applications*, and Samuel Strober, associate professor of medicine and chief of the division of immunology, was to talk about lymphoid irradiation.

Special events, including a live radio broadcast on Tuesday (Oct. 20), refreshments on Wednesday, and a visit by members of the Stanford football team, band and Dollies on Thursday, are also planned as part of the opening celebration.

The donor center is open Tuesdays from 8:30 a.m. to 8 p.m., Wednesdays and Thursdays from 8:30 to 3 and Saturday from 9 to noon. Officials said appointments are preferred and may be made by phone (415) 497-7831.

STANFORD—

Stressing a dual role of patient care and scientific innovation, Stanford University President Donald Kennedy formally opened the new Blood Center in ceremonies Friday (Oct. 16).

"By being a center for new developments in this area—a capacity we make possible through this new addition (of a Blood Center)—we can also contribute to the care of generations to follow, in this community and in others," Kennedy said in remarks prepared for delivery to a group attending the afternoon ceremonies.

A major feature of the opening program is a scientific symposium open to the public scheduled Saturday (Oct. 17) from 9 a.m. to noon in Fairchild Auditorium.

The new facility includes a donor center and processing facilities. Donor recruiter Maureen Roskoph said all of the blood is used for patients in the community, unless the donor is informed in advance that his blood is needed for research.

Specialized equipment, including an irradiator, is available to prepare blood for heart transplant patients, as well as for all hospital emergency and general medical needs.

In addition to Kennedy, welcoming remarks at the opening were to be given by Palo Alto Mayor Alan Henderson; Lawrence G. Crowley, Stanford's vice president for medical affairs; R. Hewlett Lee, chief of surgery at Palo Alto Medical Foundation, and Melvin C. Britton, 1980-81 president of the Santa Clara County Medical Society.

The scientific symposium, entitled *Perspectives on Blood Related Science in the 1980s: New Dimensions in Medical Care*, was to feature six Stanford scientists.

Pioneer transplant surgeon Dr. Bruce A. Reitz was to discuss *Heart and Lung Transplantation: A Review*. Dr. Thomas C. Merigan, professor of medicine was to lecture on *Interferon: A Useful Product of White Blood Cells*, while Dr. Edgar G. Engleman, assistant professor of pathology and medicine, as well as director of the blood center, chose the topic: *Monoclonal Antibodies: New Weapons in the Diagnosis and Treatment of Human Diseases*.

Other speakers are F. Carl Grumet, associate professor of pathology and director of the hospital transfusion service, who was to discuss the screening out of infections in transfusions. Rose O. Payne, professor of medicine emeritus and director of the tissue typing laboratory was slated to speak on *HLA and Clinical Applications*, and Samuel Strober, associate professor of medicine and chief of the division of immunology, was to talk about lymphoid irradiation.

Special events, including a live radio broadcast on Tuesday (Oct. 20), refreshments on Wednesday, and a visit by members of the Stanford football team, band and Dollies on Thursday, are also planned as part of the opening celebration.

The donor center is open Tuesdays from 8:30 a.m. to 8 p.m., Wednesdays and Thursdays from 8:30 to 3 and Saturday from 9 to noon. Officials said appointments are preferred and may be made by phone (415) 497-7831.

STANFORD—

The Board of Directors of.Stanford University Hospital has approved a Committee on the Well-Being of Medical Personnel to focus on mental illness, or the abuse of alcohol or other drugs by medical personnel.

The committee was set up Sept. 9 by the hospital's medical board, comprised of university faculty doctors and community physicians.

Members have not yet been selected for the new group, which is to develop rules to guide department heads to respond to specific incidents.

The committee also is to compile a list of organizations and individuals who can provide professional assistance to the impaired medical person, including physicans, nurses and other allied health professionals.

Sponsoring and publicizing educational programs and serving as a statistical resource for such information as incidence discovery, therapy and followup of cases are other duties.

The board is to consist of five doctors, as well as representatives from nursing services, hospital administration and the university counsel's office.

In an unrelated development, the general members of the hospital corporation formally approved the 1981-82 operating budget of $139.5 million and the capital budget of $7.1 million at their meeting Tuesday (Oct. 13).

Newly elected to a three-year term on the hospital board was Nancy B. Munger, Los Angeles, representing the Stanford University board of trustees. Reelected to three-year terms were Frank H. Roberts and Conrad F. Gullixson, both of Palo Alto; and Peter S. Bing of Beverly Hills.

Also named to the board were Dominick Purpura, the newly appointed dean of the Medical School, and Kenneth Melmon, chairman of the department of medicine, representing the faculty practice plan.

STANFORD—

"Kiss me, I don't smoke," says the frog on the American Cancer Society's button, handed out to Hospital employees last Wednesday, Oct. 7, along with balloons, posters and t-shirts, in the corridor outside the main cafeteria.

The cancer display-booth was included in "Pathways to Health," one day out of a week-long faire planned and sponsored by members of the Hospital's Environmental Health and Safety Committee.

Besides the above-mentioned paraphernalia and many brochures, the Cancer Society provided employees with an audio-visual lesson on monthly breast self-examination and photos of actual human lungs in three different states: normal, cancerous, and emphysematous.

The American Red Cross also had a booth, complete with blood pressure screening by Palo Alto area volunteer nurses. Included in their display were handouts on several courses and information on donating blood.

On hand too was the Diabetes Society of Santa Clara Valley, with cookbooks for diabetic children, wallet cards, and a list of various community services. Sign-up cards were available for newly-diagnosed diabetics, who can be matched up with trained diabetic volunteers for emotional support.

A nutrition display by Stanford's Department of Dietetics included a test-yourself quiz, dietary counseling, and flyers which reminded people to avoid too much sodium, fat, saturated fat, cholesterol and sugar, to read food labels carefully, to choose snacks wisely, to watch calorie intake, to eat foods with adequate starch and fiber, and to include foods from the basic four food groups (meat, milk, fruit/vegetable, and bread/cereal) in their daily diets.

The Health Improvement Division of Stanford's Heart Disease Prevention Program also participated in the day's events, announcing its first official series of health courses to be offered quarterly for Stanford employees—on exercise, weight management, and Q.U.I.T. smoking.

Two Stanford graduates calling themselves "Fitness Unlimited" demonstrated aerobic dancing in the afternoon. And films shown covered features of CPR and the Heimlich maneuver (used to stop choking).

Dr. Kenneth Dole, representing the American Cancer Society, discussed detection, treatment and prevention of cancer, and outlined various warning signals and safeguards.

Other events of the week were "Attack the Back" day, with a focus on body mechanics; "Environmental Safety is more than you may think," including inservice sessions on chemical, gas, and radiation safety, as well as hepatitis control; and "Bad Wires cause more than shocks," a presentation on fire and electrical safety—including members of the Palo Alto Fire Department, equipment sold to employees at low rates, and a layout of the Hospital's fire safety evacuation plans.

For the latter two programs, the Hospital met the requirements of the Joint Commission on Accreditation of Hospitals, and the California Office of Occupational Safety and Health Administration.

-more-

Tuesday's event, called "Are you ready for the Big One?" included a demonstration by SPECS (Southern Peninsula Emergency Communication System), a group of amateur ham radio operators who explained their role in the event of an earthquake. By way of illustration, they actually set up equipment to communicate with other cities.

"One of these days we're really going to get an earthquake—we know that," said Walter Read, emergency coordinator of the 25-year-old, 130-member organization. He explained that since phone lines can become unusable right away in an emergency, "we know we'll be a big help to the authorities."

Several operators are assigned to each of various agencies in the area, including hospitals, colleges, police departments, and the Red Cross. In the case of an emergency, they are able to set up communication between these agencies immediately.

"We don't originate any messages, we're just the back-up," said Read. The operators report to whoever is in charge at the scene, be it a doctor, nurse, or police chief. Their connection with Stanford University Hospital is the Emergency Staff Room, and Read demonstrated a ham radio-to-telephone conversation with the Department as part of his presentation.

"We're busy all the time," he said, explaining that the operators routinely handle urgent personal messages, providing an alternative to the phone system. Local amateurs living all across the nation are coordinated in their efforts by the National Traffic System.

"It never fails, and it's free," said one member proudly. A better sales pitch would be hard to find.

Also included in Tuesday's presentation were graphs illustrating the California faults, films provided by the Stanford University Earthquake Hotline, informational brochures, and a talk by Stanford seismologist James M. Gere.

All in all, the week's events went smoothly, with substantial employee turnout for the faire.

"We hope to make the health and safety faire an annual event for employees," said Ruben Perez, assistant director of Hospital Safety and chairman of this year's planning committee.

"Many individuals here at the Hospital deserve a lot of credit for making the program a success," he added.

STANFORD—

Doctors may have to find new ways to organize their practices to keep pace with the public's and science's newfound awareness of preventive health, says the head and founder of the research-oriented Stanford Heart Disease Prevention Program (SHDPP).

The organization seeks to develop scientific evidence showing the effectiveness of various public health programs.

"We've been in an era when the country was waking up to the importance of prevention and to the importance of health promotion, health improvement, and health maintainance," said Dr. John W. Farquhar as he reflected on the SHDPP's first decade.

"We've worried about the fact that the medical profession still hasn't really awakened to the fact that the concepts of health and prevention are changing.

"On one level doctors' future economic livelihood is threatened unless they wake up. On another level, they've abdicated an important responsibility," Farquhar said.

The SHDPP was set up in 1971 to pool the resources of several academic disciplines to pursue research on how to educate the public to take action which will reduce the risk of heart attack and other ailments.

"For example, SHDPP community educational efforts which used radio, television, pamphlets and small classes was a successful field demonstration, persuading persons who had no heart disease symptoms to exercise, give up smoking and follow a healthy diet."

The studies, Farquhar believes, can be applied throughout the country in an effort to stop disease before symptoms appear. But one difficulty, Farquhar noted, is that physicians must be incorporated in the process, and this means they must learn some new techniques and adopt some new attitudes.

"Doctors are hooked into the idea of a procedure. You have to have a procedure—something you actually do for the patient—which subsequently can be used as the basis for sending a bill.

"Doctors sometimes see this as units flowing through the system. More dollars are generated that way. There is an incentive to do procedures."

Change will come, Farquhar believes, when physicians and patients learn and adopt more modern techniques.

-more-

A prototype of modern health care is underway at Stanford's Preventive Medicine Clinic, "where individuals entering the system are taught right away that half of their exposure to health profesionals will be non-physicians and health counselors.

"The counselor is brought into the initial meeting. Goals for good health are set by the physician and patient after an initial medical examination. Then the health counselor helps make this happen.

"It may occur through one-on-one counseling, or it could be telephone calls or letters, or it could be the individual joining a class where there is a group setting. That creates cost effectiveness," he added.

Such techniques are especially conducive for weight loss, smoking cessation or similar health improvement programs, said Farquhar, a professor of medicine.

"Disease is far away from irradication, quite obviously. No matter what we do to encourage and improve personal health, there will be a need for more and more doctors. The physicians need not worry about losing patients because there are no more diseases left to treat.

"But they could run out of patients because they've gone to other health professionals since physicians haven't responded to meet their needs," Farquhar said.

He added that adapting to new forms of treatment won't necessarily be adverse to income, since a team of physicians and other health professionals can produce highly effective, hence lucrative practices.

"I can think of an example of a doctor in Southern California who takes care of diabetics. His group has four or five non-physicians involved in weight control counseling and nutrition.

"He reports he is getting far better results than before, and his income is fine, too."

In essence, a lot of modern medical care should be education, not treatment, he added.

One of SHDPP's first major projects was a three-community study, funded for seven years in 1971. Active health education programs were undertaken in Watsonville and Gilroy, Calif. Tracy, Calif., was used as a comparison, and no active programs were undertaken there.

Mass media, booklets and direct mail and posters were among tools used to persuade residents to stop smoking, make dietary changes or lose weight.

"I think the two most important things," recalls Farquhar, "is that the ability of the average person to change his nutritional habits exceeded our fondest hopes and seemed to be a lot easier to achieve than we had thought.

"Maybe the most remarkable was the degree of change we achieved in smoking cessation in a group of people who were given what would have been thought to have been a rather small amount of attention.

"We got a 50 percent reduction that lasted for three years. That is on a par with the best which has ever been achieved."

The group consisted of 60 smokers in Watsonville who were identified as being at high risk of having a heart attack in the future.

The participants had about 12 hours of classroom work in addition to the media attention and surveys the entire community received.

Currently, SHDPP is embarking on a new community project that will focus on two larger towns—Monterey and Salinas.

"The most promising and the most exciting new difference in the five-city project will be what we will achieve in young people. They were relatively ignored in the three community study.

"We have great hopes that we will develop methods for smoking prevention and for exercises, nutrition and weight control in young people that will get them started right in life and will help them work as educators within their own families.

"This will also, we believe, result in decreased drug abuse and alcohol use among young people."

For the future, Farquhar and his colleagues hope to expand SHDPP's traditional role beyond cardiovascular health to tackle such issues as cancer prevention, violence and accident prevention.

Also, SHDPP is moving into the area of employee health by researching the best ways to set up company-sponsored jogging, nutrition and related programs in the work place.

"We've got a prototype for employees right here at Stanford," said Farquhar. "We'd like to do others, primarily for the purpose of research.

"That after all is the primary goal of a university program. We attempt to lay the groundwork using solid empirical data which will enable others to proliferate the program, hopefully encouraging its elements to become part of our national way of life."

STANFORD—

The fourth heart-lung transplant at Stanford University Medical Center in 1981 was performed early Sunday (Oct. 11)in a 5-1/2-hour operation.

Dr. Bruce A. Reitz, assistant professor of cardiovascular surgery, said the patient, identified as Barry Davis, 40, came through the operation with no immediate complications.

He was returned to surgery several hours later to correct internal bleeding.

A day after surgery, the patient was reported in critical but stable condition, and his prognosis appeared hopeful. Doctors said his bleeding was subsiding and appeared not be a serious problem.

Transplant patients are routinely reported as critical after the surgery, Reitz noted.

"We are learning more about the procedure each time this operation is performed. The patient has a long road to recovery but the intial signs appear encouraging," said Reitz, who heads the heart-lung transplant team.

Davis, of Redwood City, Calif., was suffering from a congenital ventricular septal defect. He had a hole between his heart chambers, a condition which is correctable by surgery in youngsters now but not when Davis was a child.

In recent years, his poorly pumping heart caused damage to his lungs, necessitating replacement of both major organs.

He lived a fairly active life until about two years ago, when he was forced to quit his job in hotel management because of his deteriorating condition. Like his three predecessors, Davis was selected for the pioneering procedure after doctors determined he would almost certainly die within six months.

Davis' condition, said Reitz, is similar to the second heart-lung transplant patient, Charles Walker, 31, who returned home to New York State on Sept. 6, 129 days after his operation.

The first heart-lung transplant at Stanford was performed March 9 on Mary Gohlke, 45, who recovered sufficiently to return to her Mesa, Ariz., home Sept. 1.

The third transplant was performed July 28 on Karen Wilson, 28, of Mill Valley, Calif. She died three days later from complications encountered when scar tissue from previous open heart surgery resulted in excessive bleeding.

Three earlier heart-lung transplants were performed between 1968 and 1971 in South Africa, Texas and Minnesota. The longest survivor lived only 23 days.

The procedure was revived at Stanford this year after pioneering experiments on monkeys disclosed that a new drug, Cyclosporin A, circumvented two previously formidable obstacles: the slow and imperfect healing of the windpipe, and life-threatening infections. Precisely how the drug works is not fully understood. But it inhibits the body from rejecting the new heart without eliminating the body's ability to heal or fight off infection.

STANFORD—

Little did Joe Bennett suspect, as a child singing in the church choir in Colt, Arkansas, that he'd one day compose and record his own songs.

Even farther from his mind was the notion that the content of these songs would be based on his experiences in a hospital.

But so it happened. Bennett, who works in Stanford University Hospital's Clinical Engineering Department, says he found himself hospitalized on and off for five years, starting in 1967, at the Veterans Administration Hospital in Palo Alto.

"I remember when I awoke after being unconscious for six days, and a wonderful nurse was holding my hand. The nursing care I received during that traumatic period in my life was, overall, excellent."

Out of that experience was born a song he just recently recorded, entitled, "Angel of I.C.U." A sample of the lyrics go: "My Doc's golden touch, and her tender loving care/I got well darn fast, and got out of there."

"Angel" was Bennett's second piece, composed in 1972 following a Latin tune called "My Darling Rosita." Since then he has written many others, and performed at several SUH Christmas shows.

"I grew up near the home of country music superstar Charlie Rich (the 'silver fox')," says Bennett, "and his parents were friends of the family. They were my Sunday school teachers and led the choir I sang in. But I never did anything with my music until a few years ago."

After his hospitalization, Bennett started voice, piano and organ lessons, not to mention songwriting. When he joined the staff of SUH in 1973 as a patient television repairman, his songs were already expressing his concern for people and health.

"This is where it all started for me," says Bennett. "All of my music relates to patient care, which means a lot to me."

-more-

A prime example, Bennett's recent "C.P.R. Superstar" aims to teach as well as entertain. "I took the C.P.R. (cardiopulmonary resuscitation) course here at the Hospital," he explains. "Several people commented that it would be good to have a song to help keep the rhythm."

His song was inspired by that comment. In it he says: "This routine is good to learn./Be prepared when it comes your turn./You'll save a life and be a star/Because you knew your C.P.R."

Bennett stresses, however, that the song alone is no substitute for the C.P.R. course—which is necessary, he says, to really learn the techniques. "I just hope people will pick up this jingle, to help them with the beat." It's meant to supplement class instruction.

With the help of his new wife Edith—who is also his business manager and moral supporter—Bennett has recorded "Angel" and "C.P.R." on a 45 rpm disk. For "Angel," he had back-up from musician friends on the piano, drums, base guitar and rhythm guitar.

Bennett's record is available now in the Hospital's gift shop.

Bennett belongs to the South Bay Songwriters Association (Palo Alto) and the Songwriters Resources and Services (Hollywood). He has named his product RAN Records, using the initials of his new baby granddaughter.

"And 'E and J' Productions," he smiles, "stand for Edith and Joe."

STANFORD—

Tenth anniversary ceremonies are scheduled Wednesday (Oct. 7) for the Stanford Heart Disease Prevention Program.

Intended to honor employees of the innovative program, ceremonies will be highlighted by a 4:30 p.m. address on health education by Stanford President Donald Kennedy at Braun Auditorium in the Seeley G. Mudd Chemistry Building.

The SHDPP was founded as an interdisciplinary public health approach to the prevention and control of heart disease by Dr. John W. Farquhar, professor of medicine.

A key element of the research program has been a series of community studies seeking to learn the effectiveness of various educational methods—including a media campaign—in changing people's health habits.

Looking backward, Farquhar noted that the first three-community study in Watsonville, Gilroy and Tracy, Calif., provided strong support for the effectiveness of using health education to get people to take responsibiity to reduce the risk of heart disease by taking such action as quitting smoking or reducing cholesterol intake.

"We've been in an era when the country was waking up to the importance of prevention, health promotion and improvement, and holistic health.

"And we've seen it get commercialized, distorted.

"What we've been trying to do is give it a good scientific basis," said Farquhar.

Currently the team is conduucting through 1986 a five-city project which will attempt to set up permanent health education programs which can serve as models for other communities. The two cities in which programs are being set up are Salinas and Monterey, while three other similar communities are being used as comparisons.

Among other projects undertaken during the project's first 10 years is a Stanford Lipid Research Clinic, one of only fifteen such facilities worldwide. The clinic's current activity has been a coronary prevention program involving about 3,800 men with high blood cholesterol. This program, started in 1975, is scheduled to run another two years.

Several smaller studies are underway, including a nutritional assessment, sponsored by the Food and Drug Administration, which is comparing different methods of measuring food intake and eating habits.

Other endeavors include research into exercise physiology and investigations into self-directed health behavior changes, including a smoking prevention project to be used in schools.

EDITORS, PLEASE NOTE: This feature story is being sent to you to coincide with the announcement of a benefit planned for Oct. 13, at 8 p.m., in the Fairchild Auditorium of Stanford University Medical Center. The event will support the Assistance League's HOME Advancement Fund, started in order to continue and expand its services. The benefit, open to the public, will include a champagne reception and lecture by Brian Sinclair, the real person behind the character named "Tristan" in James Herriot's book, *All Creatures Great and Small.* Tickets are available, at a tax-deductible price of $7.50 each, at the Tresidder Union on campus, the Peninsula Box Office, and the Assistance League's Chapter House, 169 State Street, Los Altos.

STANFORD—

There's no place like home, as the saying goes.

But having a place to hang their hats near the Hospital can be a life-saver for long-term outpatients who live far from Stanford.

Like James Sellick, a former New York policeman who recently spent a month here for specialized cancer treatment, many out-of-towners find the cost of rental housing or motel accommodations in this area prohibitive, considering the various other expenses they accrue in association with extended medical care.

"And it's very hard to even *find* housing near Stanford," says Sellick, reiterating a common concern which often turns into a pressing need for patients.

It was in recognition of this need that, almost four years ago, the Assistance League of Santa Clara County created a committee called "HOME," short for "Housing of Medical Emergencies." Under the HOME program, subsidized housing was made available to a few Stanford outpatients and their families, according to finanical and medical need.

According to Kay Clair, chairwoman of the committee, "We hated to see people living in waiting rooms while worrying about their desperately ill relatives."

The League started out contracting for two one-bedroom apartments in the Oak Creek apartment complex across Willow Road from the Hospital. Since then, two additional units have been added to the group. "And we have served nearly 60 families," she says.

Each apartment houses two people: the patient and a relative. And the charge is only $10 a day, including utilities, for up to nine weeks. Presently, heart transplant recipients and cancer outpatients occupy the units.

"HOME has never had a waiting list of fewer than eight patients," says Clair, explaining that all screening and living arrangements are made by clinical social workers at the Hospital.

In addition to its other activities as one chapter of a national nonprofit volunteer service organization, the Assistance League runs an on-going fund raising program in the form of a costume rental shop—the largest on the Peninsula—housed at its Chapter House in Los Altos. "Most of our costumes are made by members," says Clair, "and Halloween is our busiest time of year."

Funds raised at the shop support HOME as well as other projects geared towards blind children and senior citizens.

-more-

Obviously, there is hope that someday, HOME will be able to accommodate more patients who need its services. "I would probably not have been able to come to Stanford," says Sellick, "without the availabilty of nearby, low-cost housing. It was essential for my treatment."

He adds, "It took away a lot of the anxiety and unnecessary discomfort, and having my family with me made the treatment less stressful. There really isn't any way I can express my gratitude."

Sellick did not even rent a car while he was here. He walked to and from the Hospital eight to ten times a week for his therapy.

"The Oak Creek units are so handy for the patients," says Clair. "Their proximity to the Hospital, public transportation, and shopping make them very convenient."

Clair feels that one reason Oak Creek Apartments was more receptive to the League's cause than other complexes they approached was "because their manager had died of cancer and they saw the many months of treatment required."

Says Jean Miller of Anchorage, Alaska, who lived in one of the units with her 18-year-old son while he underwent treatment, "The people in the buildings were so nice. Even the neighbors seemed to know what the program was about, and made us feel very comfortable there."

The HOME apartments come fully furnished, and are equipped with self-cleaning ovens, garbage disposals, dishwashers, and a central laundry room.

"You wouldn't want for anything," attests Betty Wise of Porterville, who stayed in one of the apartments during most of September.

The HOME committee consists of nine members who "fix up" the apartments between occupants, and purchase any necessary supplies. "Most of the time," says Clair, "the apartments are left just as they were found, so there's no great labor involved in getting them ready for the next patients."

All furnishings, says Clair, excepting beds, linens, and kitchen supplies, were donated by League members and friends. "Everyone rallied together when we got the apartments."

She adds, "No family is untouched by cancer, so if you can help a little bit, why not?"

STANFORD—

Young children with physical problems occurring at birth may have a greater risk of suffering long term social problems than other children, a Stanford University psychiatrist believes.

Dr Herbert Leiderman, professor of psychiatry, said such difficulties occurring at birth as congenital heart disease, club palate, club foot and even premature birth in otherwise normal infants, can sometimes lead to a child's difficulty with his peers.

A preliminary study, now in the final of three years, suggests that both family and peer experiences before age two may contribute to later social difficulties in this group of children.

While conclusions are still uncertain, Leiderman speculates that overconcern from parents and lack of contact with peers might in some cases be an experience which contributes to the social disability.

Leiderman and his colleagues at the Boys Town Center at Stanford received a three-year grant from the March of Dimes Foundation, supplemented by funds from the Boys Town Center to study the social development of physically handicapped infants and youngsters. Plans currently are being made for a more definitive study of the how physically handicapped children develop socially.

The goal said Leiderman, is to develop assessment procedures for potentially high-risk children and to find appropriate ways to prevent social problems from developing in children under about three years of age.

In the preliminary study, Leiderman and his colleagues observed various groups of children—some handicapped and some not—to determine how they interacted with one another. Recorded were such characteristics as how many times the child initiated play, or how many times he or she joined in play activities voluntarily.

STANFORD—

Harold L. Mindell, who was appointed director of the Stanford University Hospital Modernization Project (HMP) effective Oct. 1, has resigned the position due to personal reasons, announced Dr. Lawrence G. Crowley, vice president for medical affairs and president of the Hospital.

Mindell, associate administrator for engineering at Yale-New Haven Hospital, had planned to join the Stanford staff full-time on Nov. 1. He was to be responsible for overall management, design, and construction of the $115 million Hospital expansion and renovation plan, financially the largest single construction project ever undertaken by the University or the Hospital.

Elvia Garwood, deputy director of the project, has been appointed to replace Mindell as director effective immediately, Crowley announced. Garwood had served as acting director of the project since last February.

"In this role she has very effectively launched, guided and kept this project on schedule to date," said Crowley. "She has demonstrated excellent skills in the architectural selection process and the programming and pre-design phase."

Before becoming acting director of the HMP in February, Garwood was manager of major projects in the Medical Center Facilities Department. From 1976 to 1979 she was a project manager in the University Facilities Office.

In addition to the HMP, Garwood has contributed to other major Medical Center projects such as the completion of the third floor of Fairchild, early planning of the Boswell Clinic renovation, and the Stanford University Blood Center.

Garwood graduated from Cooper Union for the Advancement of Science and Art in New York City, and she holds a master's degree in architecture from Yale University.

STANFORD—

Perspectives on Blood Related Science in the 1980s: New Diminsions in Medical Care., is the topic of an Oct. 17 public scientific symposium dedicating the new Stanford University Blood Center.

The symposium is among five days of special events sponsored by the specialized donor facility serving Stanford University Medical Center..

Among the six speakers is Dr. Bruce A. Reitz, whose topic, *Heart and Lung Transplantation: A Review*, reflects his experience in the pioneering surgical technique. He is an assistant professor of cardiovascular surgery and spearheaded the research leading to the first successful heart-lung transplant operation earlier this year.

Dr. Thomas C. Merigan, professor of medicine, will talk on *Interferon: A Useful Product of White Blood Cells.*

Monoclonal Antibodies: New Weapons in the Diagnosis and Treatment of Human Diseases, is the topic of Dr. Edgar G. Engleman, assistant professor of pathology and medicine, as well as director of the blood center.

The symposium from 9 a.m. to noon will be held in Fairchild Auditorium at the Medical Center. Other events, starting with a ribbon cutting ceremony and champagne reception at 4:30 p.m. Friday, will be held at the donor center at 800 Welch Road.

Among speakers at the opening event will be Stanford President Donald Kennedy, Palo Alto Mayor Alan Henderson, Dr. Lawrence G. Crowley, Stanford's vice president for medical affairs; R. Hewlett Lee, chief of surgery at Palo Alto Medical Foundation; and Melvin C. Britton, 1980-81 president of the Santa Clara County Medical Society.

On Tuesday (Oct. 20), Buddy Hatton of KSFO radio will host a live broadcast from the center. The next day, special refereshments for donors will be provided, and on Thursday, members of the Stanford football team, band and Dollies will be special guests of the center.

The new center, which can handle up to 65 donors daily, is equipped with specialized equipment, including an irradiator, which is needed to prepare blood for heart transplant patients.
All of the blood, said donor recruiter Maureen Roskoph, stays in the community, and all blood is used by patients unless a donor is informed in advance that his blood is needed for research.

The donor center, which began accepting public donors Aug. 25, is open Tuesdays from 8:30 a.m. to 8 p.m., Wenesday and Thursdays from 8:30 to 6, Friday from 8:30 to 3 and Saturday from 9 to noon.

Roskoph said appointments are preferred and may be made by phone, (415) 497-7831.

She added that donors receive credit for themselves or someone they designate each time they give a unit of blood.

STANFORD—Barry Davis, 40, was released from Stanford University Hospital Wednesday (Nov. 25), 46 days after becoming the institution's fourth heart-lung transplant recipient.

Dr. Bruce A. Reitz, assistant professor of cardiovascular surgery, said Davis, of Redwood City, Calif., will be returning to Stanford for twice weekly clinic visits and continue at home with a physical therapy program, including bicycling and weightlifting.

"We're very pleased with the way the program is going," said Reitz, who performed the Oct. 11 transplant. "The results have encouraged us to go forward and continue to screen for persons who might be suitable for the procedure."

Reitz said Davis' prospects for returning to normal activity, including a career, were good.

Davis suffered since birth from a ventricular septal defect, a hole between the two primary chambers of the heart.

He had suffered symptoms since he was 15 years old and was forced to quit his job in hotel management about two years ago because of physical deterioration.

His lungs ultimately were damaged beyond repair, because his defective heart caused an overload of blood into the lungs.

Davis was selected for the heart-lung transplant procedure after doctors determined that he could not survive more than a few months without it.

Davis' stay in the hospital was one day shorter than Charles Walker, 31, who was released 47 days after his May 1 operation. He returned Sept. 6 to his Binghamton, N.Y. home, where he is reported healthy and active in sports. Mary Gohlke, 46, received her organs March 9 and spent 85 days in the hospital. She is reported progressing and is back at her Mesa, Ariz. home with her family.

The third recipient, Karen Wilson, 28, of Mill Valley, Calif., died of complications four days after her July 28 operation.

Heart-lung transplants were first performed in South Africa, Texas and Minnesota between 1968 and 1971, but none of three patients lived longer than 23 days, because the new foreign organs were rejected by the recipients' bodies.

The procedure was revived this year at Stanford when pioneering experiments on monkeys disclosed that a new drug, Cyclosporin A, helped circumvent two previously insurmountable obstacles: the slow and imperfect healing of the windpipe and life threatening infections.

STANFORD—

You can't live forever, but you can virtually choose how fast you will grow old.

This new view of the future, contradicting sharply the widely held picture of an ever older, ever more feeble population consuming the lion's share of the health care dollar, is the subject of a new book by Drs. James F. Fries and Lawrence M. Crapo of the Stanford University School of Medicine.

The book, *Vitality and Aging* (W. H. Freeman and Company, San Francisco, 172 pages, $15.95 cloth, $7.95 paper), its authors believe has an important bearing on future medical care planning because of the predictions it allows about the numbers and type of future patients.

These predictions suggest that the number of very old persons will not increase, that invalidism and chronic disease will occupy a smaller portion of the typical lifespan, and that the need for medical care in later life will decrease.

In the authors' view, most attempts to define the aging process and forecast health trends have ignored the interaction between two important sets of observations.

The first set consists of statistics showing that humans are mortal and that the natural human life span is fixed at about 85 years, a fact that has remained unchanged in the past 100,000 years. The second set of observations shows that chronic illness, such as arthritis and heart disease, can be postponed and that many of the functional deficits of old age can be modified, at least for a time.

Fries and Crapo estimate that under ideal conditions, 95 percent of Americans would die natural deaths between the ages of 77 and 93. And even though death from disease can never be totally eliminated, they feel the job of modern medicine to eliminate premature death is largely accomplished.

"Unfortunately," Fries and Crapo note, "these simple facts have not often been directly faced, and research in human aging has frequently been a quest for the secrets of longevity and even immortality.

"Predictions that we soon will live to be 200 years old because of Vitamin C or E, Gerovital or some other magical elixir have obscured a more reasonable quest, for increased vitality in old age."

In addition, the myths of Methuselah, of Shangri-la and the Fountain of Youth "remain as false and diverting as they have always been," the authors believe.

-more-

"As illness is cured or prevented," Fries says, "we live more often into old age, to almost the very end of our natural life span.

"Most people in approaching old age fear three problems—loss of ability to get around easily, of intellect and memory, and development of lingering disease.

"They think of old age as dependence on others, increasing loneliness and isolation."

And here is where the news gets better, according to Fries and Crapo.

Social and physical scientists have now begun to study the differences between individuals. Why do some people age more rapidly in particular ways than others? Can one identify the good factors in the "slow agers" and apply them to others for the purpose of improving the quality of life in those later years?

This is already happening, Fries and Crapo believe. Such factors can be identified, and they appear to be modifiable by manipulating lifestyle.

The downturn, for example, in heart disease deaths in recent years is the first evidence that this can be done, they say.

The authors give examples of how runners can improve steadily even as the capacity of their hearts and lungs diminishes with age. This is because the functional capacity of vital organs is never used to capacity to sustain human life.

"If we wish to improve a skill or function we must practice," says Fries.

The idea is not limited to physical skills. Studies show that training and use can improve intelligence test scores even in persons over 70, and that the loss of short-term memory associated with aging can be improved by practice.

But the study of the modifiable aspects of aging has just begun, Fries and Crapo believe, and represents a new clinical frontier.

"As we move from our present preoccupations with disease and longevity, these crucial studies represent an approach to the maintenance of full and vigorous life," Fries says.

STANFORD—

An innovative clinic, called the Stanford Medical Group, has been formed to strengthen Stanford Department of Medicine's commitment to patient care.

Headed by Dr. Michael B. Jacobs, clinical associate professor of medicine, and Dr. Armand P. Gelpi, clinical professor of medicine, the new clinic will have the primary duty of seeing patients much as doctors in private practice do.

In the past three decades, according to Gelpi, academic medical centers have tended to restrict their activities to mostly teaching and research, with a shift of emphasis away from patient care.

"The program is trying to bring this emphasis back on a small scale," he said. "I think it's a valid goal from the educational standpoint to have a clinic that serves as a model for the transition between academic medicine and the realities of clinical practice."

Presently, very sick patients are either admitted directly to the Stanford University Hospital or are seen in the General Medical Clinic, an operation that emphasizes the teaching as it does patient care, and in which doctors in training participate under faculty supervision.

The Stanford Medical Group, however, will be different.

"The first person the patient sees will be a Stanford faculty member," Jacobs explained. "The faculty member becomes a personal physician that in many ways parallels a private practice."

Students and resident physicians will still be incorporated in the new clinic, but only as "observers." said Gelpi.

The services will include night time and weekend coverage provided by 12 rotating associates, also full-time faculty members of the Department of Medicine. Hospital care would be included if the patient requires it.

"Every large academic medical center needs physicians to provide comprehensive diagnostic workups for patients, to decide which specialists they should be sent to, and be responsible for the continuity of care," Jacobs said. "We think we can fulfill that role."

-more-

Besides its direct patient care role, the group will offer a 24-hour consultation service to all clinical departments of the Medical School and to Northern California physicians, Jacobs said.

The new clinic also incorporates Stanford's successful executive health program started a year ago. The program is offered to company executives for the purpose of identifying current or potential health problems.

This preventive medicine effort draws on the techniques developed by Stanford's unique Heart Disease Prevention Program, and on Dr. Gelpi's own extensive experience in occupational health and preventive medicine, Jacobs said.

Gelpi had served for more than 12 years as chief of internal medicine for the Arabian American Oil Company in Saudi Arabia. From 1970 until recently he was a staff physician at Cowell Student Health Center at Stanford, and was associated with the Palo Alto Medical Clinic.

A goal of the new clinic, Gelpi said, is to engage patients clearly as partners in their medical management rather than as passive participants.

"I am a strong advocate of self-education and of physicians taking an advocate role with their patients," Gelpi said.

"The patient with the best information is going to make life easier for his doctor and help himself in the long run."

The new clinic includes nurse Marjorie Dunn, and services coordinator Sandy Musashi. The clinic is located within the Boswell Clinic Building in the Stanford University Medical Center.

Like all clinics which belong to the Faculty Practice Plan, the new group will be self-supporting from patient fees. The physicians are salaried.

STANFORD—

A group of Medical School faculty members has joined with colleagues from other Stanford University departments to focus the nine separate research programs they represent on issues of national health policy and service.

John Bunker, professor of family, community and preventive medicine and director of the division of health services research, recently was elected chairman of the seven-member governing council of the new Consortium for Health Research and Policy.

"The consortium includes faculty members who are at the forefront of research and analysis in disease prevention, health economics, legislative reform, technology assessment, the organization and delivery of health care, and physician and patient—or provider and consumer—behavior," Bunker said..

The concept of group health planning gained a physical boost in October, when the Board of Trustees approved a remodeling project which will move many of the members into a single office complex.

Specifically, the Board of Trustees approved $1.5 million to $2 million to renovate about 30,000 square feet of space for offices in the campus building formerly housing the Medical Microbiology Deprtment, which recently moved to new quarters in the Fairchild Building.

The complete list of tenants has not been established, but among those expected to move into the consortium-sponsored office space within 18 months are health communication functions of the Stanford Heart Disease Prevention Program (SHDPP), about half the department of medicine's division of immunology, and much of the family, community and preventive medicine department, including the division of health services research, which Bunker heads.

"The research of the new consortium will emphasize the role of the consumer, or patient. This is particularly appropriate as the problems of medicine shift from those of acute disease to those of chronic disease," Bunker contended.

"Since chronic illness rarely can be cured, and since increased effort at prevention is in order, clearly the patient must play a centeral role in the preventive program," Bunker added.

"We are taking a close look at how we may improve the quality of life, rather than simply attempting to prolong its duration.

"And we are also by necessity taking a hard look at cost analysis and system design.

"Research in these areas require, in addition to medicine, a variety of social science skills, including economics, sociology, psychology and communications. Hence there is the need for an interdisciplinary research center."

-more-

Most of the consortium's members already are actively involved in health planning, and some of the components individually have made widely recognized contributions to health planning.

The SHDPP, headed by consortium member John W. Farquhar, professor of medicine, has been involved in multidisciplinary research into ways of preventing heart disease through community education. Another SHDPP principal, Nathan Maccoby, professor emeritus of communication, is a founding member of the consortium and is reflective of the social science input the consortium is seeking.

Victor R. Fuchs, a professor of both economics and of family, community and preventive medicine, has combined his interest in the two disciplines by serving as a senior research associate for the National Bureau of Economic Research.

Another national leader in the consortium is Alain C. Enthoven, Marriner S. Eccles Professor of Public and Private Management, graduate school of business. author of a book, **Health Plan**, Enthoven is an advocate of the "consumer choice plan," in which competition, instead of regulation, influences costs in medical care.

Bunker said the group is expanding regularly and currently includes about 20 members. The group is open to all faculty members concerned with health planning research who wish to actively support the consortium.

Included among the 13 founding members are Byron William Brown Jr., professor of biostatistics and director of the division of epidemiology; Diana B Dutton, assistant professor of health services research; David M. Eddy, formerly professor of engineering economic systems, now occupying a similar position at Duke University.

James F. Fries, associate professor of medicine and director of the American Rheumatism Association Medical Information System; Count D. Gibson Jr., chairman of the family, community and preventive medicine department, Halsted R. Holman, Berthold and Belle N. Guggenheim professor of medicine, co-director of the Robert Wood Johnson Clinical Scholar Program at the University of California and Stanford; W. Richard Scott, prefessor of sociology and director of the Multidisciplinary Research Training Program on Organizations and Mental Health; and Harold Sox, head of the division of general internal medicine.

The existing programs include SHDPP, the Stanford Arthritis Center (including the American Rheumatism Association Medical Information System), the Midpeninsula Health Service, the division of health services research, and the department of family, community and preventive medicine.

Also the health management program at the Graduate School of business, the multidisciplinary research training program on organizations and mental health; the ambulatory care research program of the divison of general internal medicine, and the national bureau of economic research.

Members of the governing council, in addition to Bunker, are Brown, Fuchs, Holman, Maccoby, Scott and Sox.

STANFORD—

Stuart Rosse was getting a bit burned out in his job as a pastry chef just about the time his wife, Kathy Kraus, was ready to leave work temporarily to have the couple's baby.

So Rosse suggested—a bit timidly, he admits—that maybe he could take over her duties as registrar of the Stanford University Medical School while she stayed home for a few months.

And so he did.

Every weekday since he started Sept. 1, Rosse, 25, puts on a clean shirt and shaves and reports to the desk in the private office that once was his wife's exclusive domain. The grooming regimen, the couple agrees, has been one of the most difficult transitions for the former student and chef in adapting to a new work arrangement which has been judged successful by both Medical School officials and the couple.

Julian, born Oct. 13, also seemed happy as he slept contentedly during one of his mom's frequent visits to see how Rosse was doing on his new job.

"This is definitely an extension of our life at home," said Kraus. Now the couple is in the process of converting it to a permanent job sharing arrangement, "which will give Stuart more time at home to spend with Julian," the 27-year-old Kraus said.

"I was surprised but delighted when I heard of the setup," said Dr. John Steward, associate dean for student affairs and the Kraus-Rosse couple's boss.

Another backer of both the maternity relief and prospective job sharing arrangements is Rosemary Hornby, manager of the Human Resources Group for the Medical School.

"We have tried to encourage job sharing for several years. It can be very useful in terms of sometimes getting two kinds of expertise economically under the auspices of a single job.

"For example, a few years ago we were able to hire an engineer and an architect, both halftime, to supervise the installation of some equipment. We got two kinds of needed job skills which we almost certainly wouldn't have been able to find in a single individual.

"One reason job sharing might not have been done in the past is that conceptually we're not really into it yet. Employers just don't even think about the concept when they post a job.

"And it takes more time by the hiring person to set it up. You've got to have a very close match, since the two people have to work closely together."

Kraus and Rosse, who met while both were Stanford undergraduates and later married 4-1/2 years ago, believe that a close relationship at home has helped Rosse do the job better.

The work includes maintaining records for the 397 medical students, compiling statistical information about the student body, and helping the medical students with problems involving their records.

-more-

"Anyone doing this job, regardless of how much prior experience he or she has, will have a lot of questions about how various procedures are performed," Kraus explained. "These are questions which can only be answered by someone who has actually done this job.

"So, Stuart and I have a real advantage, because he can ask me questions at the dinner table or whenever they come up. If the Medical School had hired an outsider, that person obviously would not have had the access to talk with me about problems which inevitably come up."

The job "can become an overwhelming source of conversation," said Kraus. "A lot of people simply could not do the arrangement.

". . . I was a little worried at first," Kraus continued. If there had been any disagreements about how to do the job, it would put me in a very difficult position."

"I think when Kathy gets back to work," Rosse interjected, "I'm going to have to be a little more careful about keeping the desk straightened up and that sort of thing. At work, anyway, Kathy tends to be a bit more organized. That's one of the compromises we'll have to work out."

Rosse first suggested the maternity leave relief arrangement while the couple was visiting her parents in Oak Ridge, Tenn. in July.

"I was a little bit afraid of suggesting it at first," said Rosse, "at least partly because I wasn't sure I had the proper qualifications. But eventually I got over that and while we were walking down the street, I popped the question about the job."

Rosse majored in Germanic literature and thought at Stanford and comes from what he calls "an intellectually oriented background." The registrar's job calls for a college degree and some relevant administrative background.

"I never had any doubts that Stuart could learn to do the work," said Kraus, a music major who transferred to the position March 16 from another administrative slot in the main campus registrar's office. "But I was a bit concerned about whether he could adapt to the routine of an office job.

"Stuart never had a job where he had to dress a certain way," she said.

"I really wondered," Rosse added, "whether I could get used to shaving every day."

"And still," she said, "there are days where he'll say, 'I wonder if I really need to shave.' I won't say anything. And very soon, he'll say, 'well I guess I better,' and that's the end of that.

". . . For a while he had a lot of trouble answering the phone in a businesslike way. He'd always say 'hello' or something casual like that. He's also not the world's greatest typist, but fortunately, that's not a crucial part of this position."

The transition from pastrymaking to the office required some compromises.

"In this kind of work, it's a bit difficult to assess the rewards," Rosse said.

"Pastry baking is a sensual kind of thing. When you finish the day you see the eclair or pie. Here it's a matter of saying, 'today I moved 247 pieces of paper.'

"Yet, now I don't have to feel exhausted after a day of lifting 100 pound sacks of flour, and this enables me to be rested and function during those early morning feedings of Julian.

"And I'm still doing some parttime baking, and this is really satisfying because I can choose only the most interesting projects. I get to do what I want."

Tentative plans call for Kraus to return to work parttime about Jan. 1.

Rosse would shift to half time, "which will give me more time to spend with Julian and do some more gourmet pastry projects parttime."

STANFORD—

Carl Hitchner, managing attorney for medical affairs, is leaving Stanford University effective Dec. 15 to become a partner in the Los Angeles-based law firm of Weissburg and Aronson, the university announced today.

"Carl Hitchner's expertise and understanding of the law profession, particularly as it relates to medicine and health planning issues, has been an invaluable asset to Stanford and the medical community generally," said Lawrence G. Crowley, M.D., Stanford's vice president for medical affairs.

"We wish him well and appreciate that his unique talents have created a solid foundation for the conduct of the Medical Center during some crucial years of planning and development," Crowley added.

No replacement was announced immediately.

Hitchner joined the university's legal office in Oct. 1973 after completing law school at the University of Notre Dame, South Bend, Ind. He had served two years starting in 1968 as a certified public accountant in the university finance office. He came to Stanford from the CPA firm of Peak, Marwick and Co.

In his most recent position, Hitchner was responsible for the legal affairs of the Medical Center, including Stanford University Hospital.

Hitchner said he will open a San Francisco office for Weissburg and Aronson in early January in the financial district. The firm, which currently has offices in Washington as well as Los Angeles, specializes in representing hospitals, nursing homes and other care facilities.

He is a Westlake resident.

FOR IMMEDIATE RELEASE
STANFORD—

Stanford's unprecedented effort to license the entire genetic engineering industry for use of its basic scientific techniques is off to a strong start, according to Andrew Barnes, coordinator on this license for the University's Office of Technology Licensing.

Seven companies already have signed up, and at least 20 more have made a commitment to do so within a month, including U.S., Japanese, and European firms. "Our latest estimate is that 50 will be signed by Dec. 15," Barnes said Monday, Nov. 16. "New ones are calling in daily. We're concerned about an overload the last few days before the deadline."

Firms which already have signed include Green Cross of Japan, Schering A.G. of West Berlin, Smith-Kline, Eli Lilly, Schering-Plough, International Minerals and Chemicals, and Advanced Genetic Sciences, a venture firm planning applications in agriculture.

Barnes said representatives of 60 companies showed a "very lively interest" in licensing when he visited Japan, as did 14 European firms during a trip to the Continent.

"The license agreement itself has been very well received, with many compliments on its construction and administration," Barnes said. First-year revenues, initially forecast at $200,000 to $300,000, may approach the $1 million mark, he estimated.

That total would be reached if 50 firms paid a $10,000 sign up fee plus an additional $10,000 annually. Those signing by Dec. 15 may credit five times these basic fees against future royalties on resulting products. This credit is limited to 50 percent of the earned royalties annually.

Thus, for example, a company which signed up and then took three years to develop a commercial product would have a credit of $200,000 to apply against the first $400,000 in royalties.

While there's been "some grumbling" that the patent is too broad, and occasional rumors of a legal challenge, the overwhelming response to date has been positive, Barnes said.

"Many small companies have delayed making a decision, indicating they want to analyze the licensing agreement. But now, as the deadline nears, we're getting bombarded with calls.

"The program is going well. Things are happening quickly now that several firms have signed up."

The licensing program is based on a broad patent covering the basic gene splicing and cloning methods invented by Dr. Stanley N. Cohen of Stanford and Dr. Herbert W. Boyer of the University of California at San Francisco. Both inventors waived their rights to personal royalties.

When the licensing effort was announced Aug. 3, Stanford President Donald Kennedy noted it was designed to "assist the process of technology transfer by making sure lots of players get into the game. This increases the probability of valuable new applications for human science."

Niels Reimers, director of the Office of Technology Licensing and past president of the National Licensing Executives Society, believes "there's no precedent for this sort of program, seeking to license all companies who are using what is essentially the basic tool needed in genetic engineering. These companies are in widely ranging markets such as pharmaceutical, chemical, agricultural, and energy."

The earned royalty rate is one percent of net sales of end products ranging up to $5 million in value, three quarters of one percent on sales between $5 and $10 million, and one half of one percent on sales above $10 million annually. Separate royalty schedules apply to bulk products, basic genetic products, and process improvement products. Use of recombinant DNA methods in noncommercial basic research will not require a license.

Fifteen percent of the royalty income will go directly to Stanford for the costs of administering the license. After payment of direct expenses, the remaining funds will be divided evenly between Stanford and the University of California.

STANFORD—

Two young faculty members in the Stanford University School of Medicine have been selected to receive research fellowships from the John A. Hartford Foundation of New York City.

Dr. Gary Schoolnik, assistant professor of medicine and medical microbiology, and Dr. Jeffrey Sklar, assistant professor of pathology, are two of the twelve 1981 awardees, selected from a group of 86 highly qualified applicants.

His funding to begin Sept. 1, 1982, Schoolnik will examine the molecular basis for the capacity of gonococci, the bacterium responsible for gonorrhea, to cause disease. In particular, he will study the mechanism by which gonococci colonize human mucous membranes.

Schoolnik is chief of the Infectious Diseases Division of the Veterans Administration Medical Center in Palo Alto.

Sklar's research concerns the molecular genetics of a chromosomal change seen in malignant white blood cells of many patients suffering from a common form of adult leukemia.

Through his study, to receive Hartford support starting July 1, 1982, Sklar hopes to answer a number of questions about the nature of this chromosomal change—not the least of which is whether it is a cause, and not just an effect, of this form of cancer.

Inaugurated in 1979, the John A. and George L. Hartford Fellowship Program is designed to add to the supply of medical researchers by supporting the work of promising young physicians who wish to pursue biomedical studies. Each award provides annual salary support for the Fellow, and an overhead allowance to the sponsoring institution. It is for up to $113,400 for three years.

"These types of grants are very important," says Sklar, "because in many ways the beginning of a research career is the most important period, and with funding being tight the situation is even more tenuous. If young investigators don't get funding, then ten or twenty years from now there won't be anyone doing research."

The Hartford Foundation is a private philanthropy established in 1929 by John A. Hartford. Its assets today amount to $135 million.

STANFORD—

When cancer patient Imogene Seaberg of Cupertino heard she had to come to Stanford every day for six weeks to receive radiation therapy, she didn't know how she would do it.

"It's bad enough to find out you have cancer," she says, "without having to worry about your transportation to and from treatment."

But Seaberg, whose husband takes the car to work, had to worry. "Even if I had had access to a car, I sometimes didn't feel up to driving."

Seaberg's dilemma is common to many outpatients who require long-term treatment. For them, getting to and from Stanford or other area health facilities can pose a major problem.

Recognizing the special needs of these patients, the American Cancer Society (ACS) and the Palo Alto area Red Cross operate programs to transport patients to and from medical appointments.

The oldest of the two, ACS's "Freewheelers" was started 18 years ago. It has been facing such a demand that it needs more volunteer drivers. The drivers must be willing to use their own cars and fuel to provide the service.

According to Bob Hammer, chairman of the Santa Clara ACS transportation committee, there are now about 45 drivers in his group, some more active than others.

To meet demand, Hammer and others have tried picking up as many as three patients at a time. But, he explains, this is not always feasible when different locations and appointment times are involved. Moreover, it's often necessary for drivers to stay with the patient during an appointment, not only to avoid getting lost, but for moral support.

Drivers, says Hammer, can provide an important third party where cancer is concerned. "Patients are often reluctant to burden their families too much. With an objective outsider, they feel they can really unload."

Isabel Walker, oncology social worker at Stanford, agrees. A Freewheeler is a "friendly taxi driver," she says.

Hammer, a retired electronics technician from south San Jose, began as a Freewheeler over two years ago for personal reasons. "My wife died of lung cancer. Then I had a heart attack and had to retire.

"I wanted to help people who have cancer as well as those who don't," he explains. Today, Hammer is the health fair coordinator for the Santa Clara County unit of the ACS. Besides freewheeling, he works in the unit's gift shop and lectures on the warning signals of lung cancer and colon-rectal cancer.

Hammer says, "I'm happy knowing I'm doing something that's helping somebody—and that's helping me. It's selfish in a way."

The drivers, he says, come from all walks of life. "Many are housewives, some are retired, and many are working people who drive on their day off."

-more-

They're allowed to deduct nine cents per mile from their income tax (for gas), but other than that they're on their own financially.

The patients served by the program must be ambulatory, says Hammer, because drivers are not equipped to handle accidents of non-ambulatory people. "There are other transportation services coordinated by the counties for those individuals." (An example would be the "Handi-Wheels.")

Most patients served by the Freewheelers are elderly, says Hammer, and most are widows. "The men seem less willing than their female counterparts to admit they need help," he observes, "at least until it's absolutely necessary."

To avoid a waiting list for the transportation service, a budget has been set aside in the Santa Clara chapter to hire a cab when no driver is available. "But this is a test," explains Hammer. "If it works, we will try to secure ACS funds to continue it."

The Red Cross motor service differs from the Cancer Society program in that the organization itself supplies the vehicles (three station wagons), and pays for gas and maintenance.

According to Margie Hornbeck, Red Cross director of transportation, patients served must have residence in Palo Alto, Mountain View, Los Altos, Stanford, Moffet Field, or Los Altos Hills. "But of course there are people from all over the world being treated at Stanford. If they have housing in the area during their stay, that is counted as residence."

Hornbeck, a driver herself for 10 years, says the program became active about four years ago. "We're one of the few Red Cross chapters in the area that has this kind of program, because it's a heavy and expensive priority."

There is no charge for the service—which is reserved for patients who vitally need it—and no age limit (except that children under 12 must be accompanied by an adult). At the moment, there are seven Red Cross volunteer drivers, and, says Hornbeck, "We can always use more."

Like the Freewheelers, the Red Cross prefers ambulatory passengers. Patients must at least be able to get in and out of the vehicle themselves, with help if necessary.

Anyone interested in either volunteering or finding out more about the Red Cross service should call Hornbeck at 322-2143.

The contact for the Cancer Society's Freewheelers program in Santa Clara County is Janet Perry, at 287-5973. In Alameda County, the person to call is Norma Linder, at 357-1961.

FOR RELEASE AFTER 1 p.m., Sunday, Nov. 15 to coincide with Harrison's installation.

(EDITORS: A more complete release on the American Heart Association Assembly and Harrison's installation has been issued by AHA from Dallas)

STANFORD—

Donald C. Harrison, William G. Irwin Professor of Cardiology at Stanford University Medical Center, was installed Sunday (Nov. 15) in ceremonies in Dallas as president of the American Heart Association.

The installation was part of the AHA's annual assembly, which includes scientific sessions as well as business meetings.

Harrison, chief of cardiology at Stanford University Hospital, served in various AHA posts since 1965, and last year was on the national executive committee as president-elect of the national voluntary health agency.

The AHA, headquartered nationally in Dallas, has 14 medical and scientific councils, and a nationwide network of 55 affiliates. The association claims 40,000 physican and 80,000 other members who jointly develop policies and programs for almost 2 million volunteers working on the community level.

Harrison, a 1958 graduate of the University of Alabama School of Medicine, trained at Peter Bent Brigham Hospital, Boston and in research at Harvard Medical School.

He was named chief resident in medicine at Stanford in 1963, and has served here since in a variety of posts. His research interests include cardiac pharmacology, with primary emphasis on antiarrhythmic drugs and adrenergic blocking agents. He also is acutely interested in the development of computer techniques for data analyses.

Harrison lives in Los Altos with his wife, Laura, and the couple's three children.

EDITORS: ADVANCE FOR P.M. RELEASE MONDAY NOVEMBER 16.

STANFORD—

A new highly accurate scanning technique developed by Stanford University researchers may help prevent needless limb amputation and death in certain patients who become infected following cardiovascular surgery.

The technique, called white cell scanning, shows promise in solving one of the most vexing problems cardiovascular surgeons face: the early diagnosis of infections in patients who have received artificial heart valves or artificial arterial grafts, according to Dr. D. Craig Miller, assistant professor of cardiovascular surgery at Stanford.

Patients who receive aortic bypass grafts have a fairly low likelihood of developing a graft infection, ranging between one and six percent, says Miller. However, the serious or fatal consequences for those who do become infected is "devastatingly high," he says.

Unless the infection is diagnosed and treated early, patients with grafts in the aorto-femoral region (where the aorta branches into major arteries of the legs) have a mortality rate of 50 to 75 percent and amputation is required in 20 to 30 percent of patients, Miller explains.

"But a graft infection doesn't have to be life-threatening if we can recognize it early," he emphasizes.

The new technique, which involves nuclear scanning, not only affords early diagnosis which will allow early treatment—it also is highly reliable (89 percent accurate in early clinical tests) and is non-invasive (doesn't require exploratory surgery or catheterization).

Miller reported on clinical tests of the technique in nine patients who had aortic grafts in the abdominal or chest regions, Monday November 16 at scientific sessions of the American Heart Association meeting in Dallas. His colleagues in the research were Peter McKeown, Stuart Jamieson, R. Scott Mitchell, Corneluis Olcott, John Mehigan, Bruce Reitz, and I. Ross McDougall.

McDougall, a nuclear medicine specialist and associate professor of radiology at Stanford, helped develop the white cell scan technique. The procedure involves taking a sample of the patient's blood, isolating the white cells, tagging them with small doses (about one millicurie) of a radioactive element called Indium-111, replacing the cells in the patient's blood and then performing a nuclear scan to locate areas where the white cells cluster.

-more-

White cells participate in the body's defense against infection, clustering at infected spots in the body. Such a cluster of radioactively labeled white cells (a "hot spot") thus pinpoints sites of infection during the nuclear scan; if a hot spot is detected at the site of a graft, then treatment can be started as soon as possible, Miller explains.

(The indium tagging does not diminish the normal activities of the white blood cells, Miller notes.)

"The ability of white cell scanning to help physicians make this diagnosis precisely early in the course of graft infection should result in earlier treatment and improved survival rates," Miller says.

The treatment for graft infection requires major surgery in which the infected parts are removed, the surrounding areas cleaned and new grafts implanted outside the infected area, says Miller. Because the treatment involves major surgery itself, many physicians are reluctant to treat patients until the diagnosis is absolutely certain. But the lack of early and reliable diagnostic tests has meant that treatment comes tragically late, Miller says.

Other techniques that have been used in the past to detect graft infection are ultrasound and computerized tomographic scanning. But neither technique has the specificity and accuracy that the indium white cell scanning procedure has demonstrated so far, Miller says.

Miller adds that the new technique requires further clinical testing and because it is so new, it is not yet widely available.

Arterial bypass graft and artificial heart valve surgery are fairly common cardiovascular surgical procedures, notes Miller. About 900 patients undergo such operations each year at Stanford Hospital alone, he says.

Severe atherosclerosis—a fatty accumulation that blocks blood flow through the arteries—is one condition where arterial bypass grafting is indicated. Another condition that can be treated with this type of surgery is an aortic aneurysm, in which the blood vessel wall becomes so thin that it balloons out and may burst. In this case, the aneurysm is removed and the artifical dacron graft replaces it.

The indium white cell scanning technique has also been applied by McDougall and his colleagues in detecting other types of infections, including abdominal, chest, brain and bone infections. In addition, the method has been used to label leukemic blood cells in patients in order to study the cell distribution in the body and to monitor patients' response to treatments.

Mailed Thursday, November 12, 1981.

EDITORS: ADVANCE FOR RELEASE NO EARLIER THAN A.M. SUNDAY, NOVEMBER 8 TO COINCIDE WITH PRESENTATION OF RESULTS AT THE ANNUAL MEETING OF THE AMERICAN ASSOCIATION FOR THE STUDY OF LIVER DISEASES.

STANFORD—

Results from a large study of hepatitis B patients at Stanford University show for the first time that although most patients with the infection completely recover with no lasting effects, a small number of afflicted patients are at high risk for fatal complications.

The most significant finding was that an examination of liver tissue and blood tests can identify those patients at high risk, and preliminary evidence suggests that antiviral therapy may improve their liver disease, according to Dr. Coleman Smith of Stanford's division of infectious diseases.

In a survey of 370 patients with chronic hepatitis B who were followed for five years, the Stanford researchers found that a certain group of patients (less than three percent) with extensive liver damage ran a 45 percent risk of death from liver failure and related complications.

Smith, a research associate, presented the results of the long term study Saturday November 7 at the annual meeting in Chicago of the American Association for the Study of Liver Diseases. His colleagues on the study are Drs. Peter Gregory, William Robinson and Thomas Merigan of Stanford.

Hepatitis B, a liver disease that afflicts more than 100 million people worldwide, is caused by a virus against which there is now no definitive treatment although a promising drug therapy is currently undergoing clinical testing at Stanford.

Ninety percent of those who contract the infection recover with no permanent damage. However, approximately 10 percent of patients hospitalized with acute hepatitis B infections become chronically infected. These patients range from having mild to serious illness, but it is impossible to predict where on the severity spectrum any patient will fall, according to Smith.

What the researchers did was classify chronic hepatitis B patients into three groups according to how much damage was apparent in biopsies of liver tissue examined under the microscope. They then followed the patients for as long as eight years to determine the survival rate of patients in each group.

They found that 70 percent of those with the chronic form of the disease had relatively minor liver damage even though particles of the virus were present in their tissue. Among these patients survival chances were high, nearly 100 percent at the end of a five-year period, Smith reported.

-more-

For those patients whose liver biopsies showed a medium range of cell destruction, the survival rate dropped, with 90 percent surviving the five-year period.

The highest risk group consisted of patients whose samples showed signs of extreme cell damage, or liver cirrhosis. Among this group, approximately 50 percent were alive at the end of the five-year follow-up.

Smith stressed that the number of patients in the high risk category is a very small percentage of patients with hepatitis B. The encouraging news is that they can be identified and be given medical attention as new hepatitis B treatments become available.

Smith suggested that patients who know they have the chronic form of hepatitis B should not be alarmed but might consult a physician for appropriate medical care.

Patients with the chronic form of hepatitis B are also potential transmitters of the infection. Even for those who are not among the higher risk group and therefore less in need of treatment, a cure that could limit the potential for transmission of the infection would be desirable, Smith noted.

The B form of hepatitis is transmitted through intimate contact—such as sexual relations or handling of blood. Doctors, dentists, nurses and clinical laboratory personnel, as well as male homosexuals, are among the groups with a higher than normal incidence of chronic hepatitis B.

In early clinical testing of two anti-viral drugs at Stanford, a combination of interferon and adenine arabinoside monophosphate (Ara-AMP) has shown promise as a hepatitis B cure.

Under the direction of Dr. Thomas Merigan, a $2.6 million randomized clinical study of the two drugs is being organized at Stanford with a five-year contract from the National Institute of Allergy and Infectious Diseases.

The study is intended to elaborate on earlier published Stanford studies which show that the two drugs used in combination or alone have produced cures in a significant number of hepatitis B patients.

Volunteer patients with chronic hepatitis B are still being accepted for the study.

Volunteers, who should be from the Bay Area or willing to come to Stanford for weekly studies, will be hospitalized for a few days and blood samples will be drawn. A liver biopsy will also be obtained prior to and after therapy, and one and two years later.

People willing to volunteer in the study should call (415) 497-6231.

City Desk: Story is released jointly with Children's Hospital at Stanford.

STANFORD–

Stanford University Hospital and Children's Hospital at Stanford have agreed to continue intensive planning for a unified children's medical center at the present Stanford University Hospital site.

A resolution calling for study of "a joint venture to build, own, and operate a children's hospital" has been approved by the Board of Directors of Stanford University Hospital and by the Board of Directors of Children's Hospital at Stanford.

The two boards have also taken these actions:

• authorized the firm of Naramore, Bain, Brady and Johanson of Seattle, architects for Stanford University Hospital's modernization program, to develop a schematic design of a consolidated children's hospital.

• agreed to form a joint planning committee to develop proposals on the organization and governance of the new hospital, conduct a detailed financial feasibility study, and develop fund raising plans.

According to the resolution, the committee must make its recommendations to the two boards as soon as possible, but no later than June 1, 1982. If the recommendation is to proceed with consolidation, there should be a joint venture agreement for both Boards' consideration.

The proposed new building, to be an addition to the present Stanford University Hospital modernization program, would retain the name "Children's Hospital at Stanford." The boards of the two institutions would share financial responsibility for its operation, but each parent institution would control its own endowment and other financial assets.

A unified children's medical center would consolidate the 60 beds of Children's Hospital at Stanford, the 44 acute pediatric medical, surgical and intensive care beds of Stanford University Hospital, and the combined clinical, teaching, and research programs of both institutions in a single setting of patient care.

Presently, several teaching and clinical research programs of Stanford Medical School departments—Pediatrics, Surgery, Psychiatry, and Radiology—are carried out at Children's Hospital, supplementing the core programs at Stanford University Medical Center.

Both hospitals share a common medical staff whose members are on the Stanford medical faculty.

More than 2,500 patients are transferred each year from Children's to receive specialized services available only at Stanford University Hospital.

-more-

The hospitals are a mile apart and separated by a major thoroughfare. This requires constant transportation of sick children, less than optimal overall service, and duplication of effort and facilities, the two hospital boards have concluded.

A study entitled "Final Report—Planning for Children's Services" by a task force representing the two institutions also agreed that "the health care services offered to children could be provided optimally only through unification at a single physical location".

In a joint statement, Kenneth H. Sayre, chairman of the board of Children's Hospital at Stanford, and Dr. Lawrence G. Crowley, president of Stanford University Hospital, said:

"The purpose of the proposed consolidation is to provide the best possible overall comprehensive medical care for children and to improve the complementary activities of pediatric teaching and clinical research."

Children's Hospital at Stanford, a nonprofit institution, and Stanford University School of Medicine have maintained close ties since the former was established on the campus in the 1920's. In recent years, Children's has been formally a teaching hospital of the School of Medicine, but it is independently governed and separately funded.

The potential development of a single children's medical center has been discussed in the past. Rising costs, concerns over duplication of services as well as trends in pediatric care, which result in attracting to Stanford the more difficult-to-treat cases, have played a major role in the current proposals for unification, officials explained.

Another impetus for re-examining this option was the present $115 million modernization program contemplated by Stanford University Hospital, which includes inpatient pediatric facilities.

"A rare opportunity," Crowley termed it, "to review the future of pediatric care in the community and region."

Both sides emphasized there are many details to be worked out, including future use of the existing site of Children's Hospital at Stanford. The consolidation concept requires approval by the Children's Hospital Board, and by the general members of the Stanford University Hospital Corporation. It must be financially feasible. And the two boards must reach agreement on the organizational structure.

Finally, the project must pass the review process by local and state agencies.

(EDITORS: The following release is embargoed until 9 a.m. EST Jan. 4, when James F. Fries is scheduled to deliver his paper at the American Association for the Advancement of Science meeting in Washington)

STANFORD—

Medical science may never be able to lengthen the average human lifespan beyond about 85 years, but people may expect increasing vigor and good health right up to the end, two Stanford University scientists have concluded.

In fact, the two researchers believe "the medical and social task of eliminating premature death is largely accomplished."

The implications of the research are important for society, say Drs. James F. Fries and Lawrence M. Crapo, because it destroys the myth of an ever older population increasingly in need of geriatric care and expensive facilities. As diseases are eliminated, people should live healthy lives until inevitably they are overtaken by death from old age.

Longterm care facilities need to concentrate on encouraging autonomy rather than on expanding medical care, which won't be needed by a healthier older population, the doctors explained.

Results of Fries and Crapo's research have been published in a book, **Vitality and Aging** (W.H. Freeman and Co., San Francisco, 172 pages, $15.95 cloth, $7.95 paper). Their conclusions were presented Jan. 4 in a paper, *Physiologic Aging and the Compression of Morbidity*, at the American Association for the Advancement of Science Meeting in Washington, D.C.

Central to the authors' conclusions are the dual findings that disease can be eliminated but that the human lifespan is fixed.

What the authors have done is compare how elimination of disease, particularly during the current century, has failed to alter the statistical truth that virtually everyone will die before the age of 97 unless illness or accident kills them first.

As evidence, they show that the oldest documented human being in the world lived 115 years, and claims of superlongevity among certain remote mountain peoples "have now been convincingly shown to represent systematic age exaggeration." Statistical analyses indicate that man reached the current fixed lifespan about 100,000 years ago.

-more-

Human organs deteriorate at a slow but constant rate from about age 30, and eventually they fail lethally in all of us at about the same age.

The present lifespan did not develop arbitrarily, Fries and Crapo contend, and is related in part to natural selection and the need for persons to remain productive until their offspring no longer need their protection.

But while organs deteriorate, it is still possible to increase physical efficiency throughout one's lifetime. For example, it is possible that a serious runner free of disease can increase his or her performance throughout most of life, since the organs are seldom used to their biological capacity, even by athletes.

Under ideal conditions, the median natural human lifespan is set at a maximum of 85 years, and 99 percent of Americans would die of old age between about 73 and 97, the researchers said.

Fries and Crapo do not rule out the possibility that the human lifespan could ultimately be lengthened, and point to such new techniques as recombinant DNA as potential solutions.

But, they contend, "the solutions to (lengthening the lifespan)...must involve a quantum jump in scientific knowledge....We suspect that superlongevity and immortality are at least as difficult to achieve as travel through time."

The authors show how the conquest over disease has narrowed the gap between the theoretical and actual lifespan of persons to the point now where white females in 1980 die an average of only seven years short of the theoretical limit. Of those seven years, four are accounted for by violent death.

At least one major killer of 1900, smallpox, has been completely eliminated, while tuberculosis—the no. 1 killer in 1900—has shown a decline of 99.5 percent.

Fries, an associate professor of medicine, directs the Stanford arthritis clinic and is author of the bestselling book, **Take Care of Yourself**. Crapo, an assistant professor of medicine at Stanford, is clinical director of the Geriatric Research Center at the Palo Alto Veterans Administration Medical Center.

STANFORD—

A tougher smoking policy was adopted and a controversial wartime preparedness plan was discussed by the Stanford University Hospital board of directors Dec. 10.

The board, asking for further study, postponed action until Feb. 10 on the Pentagon's civilian/military preparedness plan. The institution's medical board one day earlier had recommended to the hospital board that no contract be signed with the Department of Defense.

But the medical board suggested that the hospital should inform the government on a continuing basis about the number of beds which might be available for wartime emergency patients. The medical board represents the medical staff, composed of community and faculty physicians.

SUH, along with other U.S. medical institutions, has been asked to contract for beds and care in advance of a potential limited nuclear war overseas.

The standard agreements under the Civilian-Military Contingency Hospital Systems proposal also call for participating hospitals to report detailed personnel information, including data which the government could use to mobilize health care professionals.

The SUH medical board had objected to reporting personnel information.

Analysts have noted that civilian participation would be vital to provide care for U.S. casualties following a limited nuclear war outside the country, such as in Western Europe.

Nationally the plan has been backed by the American Medical Association. And some hospital administrators have suggested that advance agreement with the military would ensure that hospitals would continue to run their own facilities. The lack of such agreeement, some administrators contend, could trigger a military takeover of hospital management during a crisis.

Opponents, including a national anti-war group called Physicians for Social Responsibility, have said that planning for the results of a nuclear exchange creates the unrealistic expectation that a viable response is possible.

In other action, the hospital board voted to restrict patient smoking to specially designated public areas, such as certain solaria.

Smoking in patient rooms, which until now had been tolerated, would be prohibited except by patients in private rooms unable to go to designated smoking areas. These patients will need the written approval of their doctors.

The smoking policy followed recommendations of an advisory committee which noted that smoking is a fire and health hazard and should be restricted.

The committee, which issued a July 1 report, noted recent studies demonstrating that "second hand smoke" was harmful to nearby nonsmokers.

The new policy also restricts employee smoking to designated areas.

STANFORD—

For a premature infant who relies on someone other than his own mother's milk to survive, the holiday season can bring less than good cheer.

As Mrs. Teresa Asquith of the Mothers Milk Bank in San Jose explains, nursing mothers who donate milk which helps save lives are often too busy during holidays and summer vacations to continue their participation.

And the San Jose bank is the only one of its kind in California, supplying human milk to about 16 hospitals in northern areas of the state. One recipient is Stanford, whose Dr. Philip Sunshine, professor of pediatrics, has served as medical director of the bank since October, 1980.

"When a baby has diarrhea that doesn't respond to intensive medical therapy," says Sunshine, "often what he needs is human milk. But some mothers, for one reason or another, cannot nurse their own babies. That's when we need help from the milk bank."

According to Asquith, there are various medical reasons that people (not necessarily, though predominantly, babies) may require human milk. One of the bank's recipients is a child awaiting a kidney transplant; another recent user was a teenager with an unusual allergy.

"Human milk is more readily digestible than formula or cow's milk," she explains, adding that in the case of a premature infant, formula can sometimes "plug up" a tiny intestine. "There are now some formulas which are really great. But there's nothing yet as perfect as a mother's milk."

And, she notes, there are a variety of reasons that a mother may not be able to supply her own milk. "Especially in the case of premature infants, factors such as stress and the presence of medications may interfere. Also, milk doesn't flow easily without the help of a suckling infant."

"But about 70 percent of mothers who deliver at Stanford do nurse their own babies," stresses Sunshine, "and even in the intensive care nursery, we encourage mothers to express and bring in their own milk for their babies if possible."

And Asquith agrees, "The best milk for any infant is his own mother's. Only in the absence of her milk would we recommend the use of bank milk."

The bank solicits milk from nursing mothers who are healthy non-smokers with no history of hepatitis or systematic disorders, and who are not on medications or birth control pills.

-more-

Prospective donors call the bank, undergo skin tests for tuberculosis, obtain approval from their own obstetricians and pediatricians, and participate in a two-hour in-service where they learn how to express and store milk in the privacy and convenience of their own homes.

"We collect milk under a very strict protocol," says Asquith, who herself visits each donor's home to ensure sanitary conditions and explain the procedure.

"It's really quite simple," she says. First the donor washes her hands with soap and water, and her breast with water only. She opens the bottle in a sterile fashion, without touching the inside.

After she discards the first third of an ounce, the donor expresses her milk directly into the bottle. Then she caps and immediately cools it, marking down pertinent information. The bottle must then be frozen. There is only one expression of milk per bottle, says Asquith.

The use of breast pumps is discouraged to avoid danger of contamination. Donors are provided with sterile bottles, and the milk is picked up once a week by volunteer drivers.

"Many of our donors have chosen to bring it in themselves, however," says Asquith. "We have a cookie jar for the kids, and it's a way of socializing." Those willing to do this, she explains, may claim a tax deduction for mileage at the end of a year.

When brought to the bank's laboratory, the milk is gently de-frosted overnight and kept separate from all other donations. A sample is taken from the middle of the container and tested for bacterial contamination. Then it is incubated for 48 hours, and if its qualities comply with certain technical criteria, it is distributed raw (unpasteurized) and frozen, on a physician's prescription only.

If the milk is found to be at all contaminated, it must be pasteurized in vitro for 30 minutes. Again a sample is taken, and if it passes the test can be distributed. The ordering physician decides, says Asquith, depending on his individual patient's needs, whether to request raw or pasteurized milk.

"Generally, pasteurized milk is considered to be the most bacteria-free," she says. "But we pasteurize a very small amount of milk, because our high standards assure the quality of the raw milk we distribute.

"And we maintain very open lines of communication with our donors," Asquith continues. "We talk to them on the phone a lot, congratulate them on providing good samples of milk, and encourage them to send us more of the same next time. We've found that the personal touch means a great deal."

To maintain as natural a regimen as possible, the recipient baby is given milk from a nursing mother who has a baby of about the same age. Also, an effort is made to retain the same donor for a particular recipient throughout the time that milk is required.

The milk bank began as a separate entity in 1974, says Asquith, after being part of the Northern California Transplant Bank, for which she worked as a technician. Both banks operate under the auspices of the Institute for Medical Research in San Jose.

-more-

3-3-3

"We were given the impetus to separate the milk bank when a seven-month-old baby from Los Gatos developed diarrhea and needed human milk to survive. Then the press picked up the story and contacted us.

"We distributed over 1300 ounces of milk in our first year. I went out the door to pick up our very first ounce."

At that time Dr. James Harrod, of Valley Medical Center, was medical director of the bank. In the seven years of operation since then, says Asquith, 932 nursing mothers have donated milk.

Last year the bank, staffed by Asquith and one full-time assistant, distributed a total of almost 45,000 ounces. Stanford Hospital alone received almost 6,300 ounces in 1980.

How does the milk bank find donors?

"Mostly by word-of-mouth," says Asquith.

Also, the bank has a volunteer auxiliary which helps in creating community awareness and placing pamphlets "all over town."

Physicians and nurses can also pitch in. "Several nurses here at Stanford are very interested in the program," says Sunshine, "and they encourage nursing mothers to get involved."

One problem faced by the bank, says Asquith, is the increased demand for milk and the inability to meet all the requests that come in. "The need for additional milk banks is obviously tremendous," she says.

A grant from the California State Department of Health Services, Division of Maternal and Child Health, effective Nov. 1, 1981, will allow three more banks to be set up in areas of California with large neonatal populations.

The initial stage of grant activities, says Asquith, will consist of gathering and studying information collected from milk banks all over the world. "We'll meet with the advisors, devise a manual on procedures, and then we'll set up the three banks planned."

Meanwhile, she notes, women can continue donating milk to nearby hospitals that need it even while they're off on vacation.

"Wherever they're going, we'll give them supplies, instructions as usual, and a friendly letter of introduction."

Those wishing further information should contact the Mothers Milk Bank, Institute for Medical Research, 751 South Bascom Ave., San Jose, CA 95128.

The bank can be reached by phone at (408) 998-4550 or (408) 279-5103, weekdays from 8:30 a.m. till 4:30 p.m.

STANFORD—

Ross Campbell has been appointed by the Stanford University counsel's office as managing attorney for medical affairs effective Dec. 15.

Campbell has served at Stanford since June 1977 as an associate staff counsel. His duties have included both labor law and representing the Medical Center.

John J. Schwartz university counsel said that Campbell "will work closely with Gail Mondry and our other attorneys in specialized fields to provide the complex legal services demanded by a major medical center."

Campbell, 33, graduated from Stanford in 1970 with a degree in history and German. After completing law school in 1974 at the University of Washington at Seattle, Campbell worked for three years at the Department of Health, Education and Welfare in Washington, D.C.

He is a member of American Bar Association, the California and Washington bars, as well as the National Health Lawyers Association.

He replaces Carl Hitchner, who resigned effective Dec. 15 to become a partner in the Los Angeles-based law firm of Weissburg and Aronson. Hitchner will open a San Francisco office for the firm, which specializes in representing hospitals, nursing homes and other care facilities.

STANFORD—

The National Labor Relations Board (NLRB) regional director has recommended turning aside objections filed by a union which had unsuccessfully sought to represent a group of Stanford University Hospital employees.

A Dec. 1 action by James S. Scott, region 32 director of the NLRB in Oakland, stated that the objection filed by Local Union No. 39, Internatiional Union of Operating Engineers, AFL-CIO "be overuled in its entirety."

The union has until Dec. 14 to appeal the regional director's report to the NLRB in Washington before the recommendation becomes an action of the board.

On Sept. 18, a group of crafts and communications employees and biomedical technicians voted 57 to 22 in favor of no union representation.

Local 39 had contended that "the employer (SUH) gave a substantial raise to the employees and also interfered with employee rights."

In his report, Scott noted that the workers eligible to vote in the election had received wage increases on Sept. 1. But he agreed with the hospital management's position that the increase constituted a market adjustment consistent with what the employer granted all other workers and had granted the persons voting in recent past years.

"Thus, by announcing and putting into effect 1981 market value adjustments on or about Sept. 1, the employer took steps as it would if petitioner (the union) were not in the picture," the report said.

"It is evident that the wage increases in question were intended to help the employer keep existing employees and attract new ones, rather than to undermine employee support for petitioner," Scott concluded.

In addition, the report stated "no evidence was submitted in support of the Union's assertion of other interference with employee rights."

The group of workers rejecting Local 39 had been represented after 1972 by an unaffiliated employee organization, SUMCEDA, which received a plurality of votes in a subsequently challenged 1979 election. While the results of that balloting remained in limbo, SUMCEDA's leadership asked to withdraw as the bargaining unit, a move which was approved earlier this year by the NLRB.

The Sept. 18 election was ordered by the NLRB to clarify representation of the workers.

STANFORD—

The Medical/Technical Division of the Stanford Bookstore held its grand opening at 135 University Ave., Palo Alto, Wednesday, Dec. 2.

A champagne and hors d'oeuvres reception honored Mr. and Mrs. Walter G. Edwards, Palo Alto residents whose generosity in donating their portion of the co-owned building has made the new store possible.

Formerly located in the Medical Center complex, next to the student lounge, the medical bookstore was "about the size of our present supply area," said Rose Ann Sims, manager of the division.

As a result, the previous store carried only medical books, and very few student and office supplies. There was room for only one or two copies of each book on display. Now, though still limited compared to the campus store, the division carries a wider variety of books and more supplies, including calculators and small computers.

"A Medical Center of Stanford's significance," commented Roy Hoyer, book buyer of the division, "really should have a respectably sized bookstore which can offer both good quality and quantity.

"Try as they could to find us extra space at the Medical Center," he continued, "it couldn't be done and we had to look elsewhere."

During his special presentation, Eldon Speed, manager of the Stanford Bookstore, described how the building downtown was obtained.

"It was up for lease and perfect for our needs, but out of our price range. When I jokingly suggested that the owners give it to us, they naturally laughed. A few days later we received a phone call from Mr. Edwards."

And the new store opened last August.

The Stanford Bookstore is a private, non-profit corporation. The staff of the Medical/Technical Division have encountered very few customer complaints since their move away from campus. To compensate for the farther distance, Hoyer explained, they have expanded operating hours to include Saturdays and Thursday evenings.

"We're very excited about how it's worked out, and we hope to build on our success so far," he added. "The slight inconvenience is far outweighed by the advantages."

Among the honored guests at the grand opening reception were Stanford University President Donald Kennedy and Eric Miethke, who presented Edwards with a state resolution on behalf of Senator Marz Garcia and the Senate Rules Committee commending his philanthropic generosity.

Edwards was also shown a plaque in his honor, to be mounted outside the store.

"I came to Palo Alto 30 years ago," he said, "and Stanford University is a very big part of this community. In both health and welfare, Stanford has contributed to my wife's and my success in this area. So this is our way of saying 'thank you.' "

Edwards and his partner Harvey Koch are in real estate development for northern Santa Clara County.

STANFORD—

Rape, and the need for understanding and compassionate attention toward its victims, has brought about certain changes over recent years in Stanford University Hospital's procedures for dealing with the problem.

Until about ten years ago, rape victims were treated like everyone else, says Pat Taylor, R.N., assistant director of Emergency Services, and were not given any sort of priority care.

She can remember people callously saying, "Oh, I bet she asked for it."

But according to Taylor and Jane Anderson, Hospital liaison for the Mid-Peninsula Rape Crisis Center, there has been a huge turn-around in societal attitude recently—reflected in the policies of such agencies as police departments, state legislatures, judicial systems, and hospitals.

California district attorneys are being tougher on rape suspects, they say, just at about the same time "helping" professions are showing more compassion towards victims.

At Stanford, a written policy has been in effect for about five years regarding the treatment of rape victims in the Emergency Department. The rape protocol calls for seeing the victim immediately, providing maximum emotional support without being moralistic, and minimizing interrogation. "Allow victim to verbalize as she wishes," it reads.

Sexual assault cases are not to be discussed with anyone without specific victim consent, which must also be obtained for medical and legal examinations, and photographs (for the police). The nurse determines who brought or referred the victim, and speaks with the escort if possible.

She assesses the social history surrounding the assault, as well as the victim's present functioning. The pediatric/adolescent resident must be notified for victims 17 or younger.

If not previously informed, the police are contacted to come to the Hospital, day or night, to obtain a report and collect evidence.

The physician's role includes: obtaining a medical history, performing a physical exam, and obtaining medical-legal evidence.

Many precautions are taken, including tests for venereal disease, and administration of tetanus shots and antibiotics when necessary. Injuries are treated, and the victim's wishes are followed concerning hormonal pregnancy prevention, abortion, and menstrual extraction. The physician may request consultations, initially or in a follow-up as indicated.

When the workup is completed, the patient is encouraged to follow up with her private physician, or given an appointment in the Gynecology or Pediatric Clinic in one week. She may also be given an appointment in the Psychiatry Clinic. A test for V.D. should be repeated in eight weeks.

The Emergency Department nurse arranges for an escort home if needed, as well as for temporary housing and clothing.

"Follow-ups, though," says Anderson, "are a big problem because victims often don't come back even if directly asked to." At that point a social worker contacts them again.

"A lot of the initiative is taken here at the Hospital," she says.

-more-

"I think the police in Palo Alto are very sensitive too," says Taylor, "which helps a great deal. They usually come right into the department with the victim."

Anderson agrees. "They used to come in with a 'look how she's dressed' attitude, but recently there's been an emphasis on sensitivity training." She adds that besides police, the crisis center, supported by a grant from United Way, also refers rape victims to the Hospital. An average of one rape case is encountered each week by the Hospital.

Adds Taylor, "Ten years ago we didn't get very many rape reports here—it really was a rarity. Many victims would go to private doctors, and since only institutions were required to report the cases, many of those victims were left out of the statistics."

"It's very hard to tell," says Anderson, "whether we have more rapes reported or more actually happening. But officials believe there are more being reported." (In Santa Clara, they say, the percentage of attacks that are *reported* is thought to be higher than in previous years and higher than in most other areas.)

"People are talking about it now," says Taylor. "Years ago rape victims never wanted anybody to find out. We had a nurse who was raped, and the whole department just rallied around and moved her out of her place that night. I found out at that time that two other nurses had been raped earlier in their lives, and up until that time nobody knew about it."

"I think rape is a big subject right now," says Anderson, "and when a quiet victim sees other women talking about their experiences it gives her strength to do the same."

"Many times," she emphasizes, "the victim is calm right after the attack but will feel the psychological effects later. Fifty percent of rape victims lose their husbands. It starts with a resistance to be touched and continues as an aversion to sex and even a fear to go back to where they lived."

"If everything could hit the papers," says Taylor, "the rape problem would be more easily solved. But some things aren't reportable. The victims understandably don't want any press."

The need for privacy is one reason that, unlike many counties, says Anderson, the police in Palo Alto will take rape calls "blind"—without names. It's also why Hospital staff attempt to get the patient into an area where she isn't discussing what's happened in front of a lot of people.

"The emphasis," explains Taylor, "is on getting the patient in, while having just one nurse follow her through the process. We are attuned to the fact that it's more than a physical need; she has a mental need for support as well."

This is especially true, says Anderson, because the court procedure later can be difficult. "You have to constantly prove that you were attacked."

"There are still many old ideas about rape around," concedes Taylor.

STANFORD—

Stanford University's fifth heart-lung transplant of the year was completed Tuesday (Dec. 1).

After a 3½-hour operation, the patient was reported in critical condition but her vital signs were stable, said Dr. Bruce A. Reitz, assistant professor of cardiovascular surgery.

"There were no complications in surgery and the patient is doing as well as could be expected after an operation of this magnitude," Reitz said.

The patient was identified as Darlene Moore Mathern, 37, of Waterloo, Iowa. She suffered from pulmonary hypertension, a condition which she developed about 13 years ago and which had progressed to the point where doctors were convinced she had only a few months to live.

The malady results in high pressure in the arteries serving the lungs. The arteries become constricted, blocking the flow of blood and requiring the right side of the heart to work harder and eventually become damaged.

There is no known cause or treatment for the condition. Therefore, Reitz said the only current hope of patients suffering from this disease is heart-lung replacement.

Stanford's first heart-lung transplant, Mary Gohlke, 45, also suffered from pulmonary hypertension. She was released from the hospital June 1, 85 days after her surgery. She has returned to her home in Arizona.

Three other heart-lung transplant patients were born with congenital heart defects which subsequently damaged their lungs.

Charles Walker, 31, who was operated on May 1, was released from the hospital 47 days after his surgery. He returned to his home in New York State, where he is reported healthy and pursuing an active personal sports program. Barry Davis, 40, received his new heart and lungs Oct. 11. He was reported in satisfactory condition and making progress during Thanksgiving week. He was moved to a general care ward Nov. 9 after an intensive care unit stay of 30 days, the shortest period for any of the surviving heart-lung transplants.

Another heart-lung transplant, Karen Wilson, 28, died of complications Aug. 1, four days after surgery.

"The heart-lung transplant procedure is performed only as a last resort for terminally ill patients," Reitz explained. "And we are encouraged about its therapeutic potential for a group, albeit small, of patients for whom there is no alternative."

The first three heart-lung transplants ever were performed between 1968 and 1971 in Texas, Minnesota and South Africa. The longest any patient survived was 23 days.

The procedure was revived at Stanford this year after clinical tests indicated that a new drug, Cyclosporin A, appeared to be more effective than previous medications at controlling rejection, the natural response of the body to fight off the foreign tissue in the new heart.

Cyclosporin A, a fungal derivative produced in Switzerland for Stanford, appears to offer the dual advantage of fighting rejection while not interfering severely with the ability to fight off infection or with the body's normal healing process. Previous heart-lung transplants died because their severed windpipe failed to heal.

TEST BEING DEVELOPED TO AID BEE STING VICTIMS

STANFORD—

If a doctor had an inexpensive, simple and reliable blood test for detecting people's sensitivity to bee stings or other allergic reactions, he could prescribe better therapy, bringing a new measure of relief to the sufferer.

Such a blood test may soon be developed, thanks to recent findings reported by researchers from the Department of Pediatrics of the Stanford University School of Medicine and the Allergy and Clinical Immunology Clinic in Paris at the annual Congress of Allergists in Bal Harbor, Fla. last week.

In allergy, including bee stings, proteins called IgE antibodies are formed in the blood tissues and trigger an immune reaction in the body against the foreign allergens. IgE is one of five classes of antibodies, known to exist in humans, and termed IgG, M, A, D, and E. Each of these has different physical properties and a different role in the immune process. Protection against allergic reactions is believed to reside in the IgG class.

There are also subclasses of immunoglobulins, and one of these, IgG4 for short, has been implicated as the blocking antibody for bee stings.

To determine if IgG4 is the blocking antibody, the researchers George M. Halpern, J. Blessing-Moore, Hao-Pi Hsu, and Richard B. Moss studied three types of people exposed to bee venom: allergic and non-allergic bee keepers, patients with anaphylactic or acute allergic reactions which can result in shock or even death if not properly treated, and bee-sensitive patients on hyposensitization injections with bee venom.

Using an enzyme-linked immunoassay they developed specifically to measure this subclass of antibody, the researchers determined that in patients who had received shots for bee stings there was a rise in IgG4 to levels normally found in the serum of bee keepers who presumably have developed immunity to bee venom, explained Dr. Moss, an assistant professor of pediatrics.

In their test, the researchers coat small plastic wells with bee venom allergen. They add a sample of test serum and pig antibody which reacts against the human IgG4 subclass. Then they add rabbit antibody against the pig antibody to which an enzyme has been attached. A substance in whose presence the enzyme turns blue is introduced into the well.

The intensity of the color change in the well, which can be seen by the naked eye or measured by a spectrophotometer, is proportional to the amount of IgG4 antibody to the allergen present in the test serum.

"This test avoids problems and hazards associated with the traditional radioimmunoassay methods while achieving equal sensitivity and specificity," Dr. Moss said.

While additional research will be needed to confirm that IgG4 is the blocking antibody, the clinical implication is that doctors may soon have a simple, inexpensive immunoassay technique for measuring antibodies of different classes, subclasses and specificities.

Such a technique would provide a much needed guide for the allergist who must know when and for how long his patients need their shots, said Dr. Moss.

(Dr. Halpern, director of the Laboratory for Immunology and Allergology in Paris, has spent the past year as a visiting professor in the allergy division of the Department of Pediatrics at Stanford.)

SCIENCE FOCUSES ON PREGNANCY-RELATED MENTAL ILLNESS

STANFORD—

The risk of pregnancy-related mental illness within the first month postpartum is significantly higher among women who experience abnormal labor or whose infants are stillborn or die within the first month of life, according to Dr. Ralph S. Paffenbarger, Jr., professor of epidemiology at the Stanford University School of Medicine.

"The hazard for mental illness is highest in the first month after delivery," he said. The risk is also increased in women with gestational periods of less than 40 weeks and in those whose babies at birth weigh less than 3,350 grams (7½ lbs.).

In contrast, mental illness developing during pregnancy strikes older women who have had more children and a longer interval since their last viable pregnancy.

The risk of pregnancy-related mental illness is not influenced by the scheduling or amount of prenatal care, differences in obstetric procedures or anesthesia, the sex of the infant or whether the infant is breast or bottle fed.

Paffenbarger spoke on postpartum mental illness at a recent symposium on the changing risk of disease in women at the Johns Hopkins University School of Public Health. He based his comments on a study of the psychiatric records of 1,142 childbearing women treated by public and private psychiatric services in Hamilton County, Ohio, from 1940 through 1958 as well as more recent findings.

His research has been concerned with the more severe forms of pregnancy-related mental illnesses that require hospitalization as contrasted to the common relatively benign "postpartum blues" from which most women spontaneously recover.

According to available figures, the incidence of severe emotional illness following childbirth is about 1 to 2 per 1,000 births. A common example of such illness is obsessive, compulsive behavior often taking the form of rumination about the safety of the baby and intense preoccupation with the details of his care. This behavior may evolve into severe psychosis lasting weeks or months. Other postpartum disturbances have included confusion or delirium together with depression or excitement.

-more-

2-2-2

Women giving birth to a first child are at significantly higher risk of postpartum mental illness than women who have already borne children, Paffenbarger said. Those who have had a severe postpartum reaction are at increased risk of developing mental illness in future pregnancies, especially women who were 25 years or older at the time of the first attack.

"The sudden development of mental illness in the month after the birth of offspring coincides with violent hormone readjustments," Paffenbarger said.

He noted that in women who had subsequent pregnancies the onset of mental illness occurred at exactly the same stage as the original attack—a finding, he added, that should encourage specific endocrinological research.

Paffenbarger said that the incidence of first mental illness during pregnancy was only minimally higher than that among women of comparable age who were not pregnant.

"It leads us to ask whether the low incidence rate during pregnancy is the result of some protective psychological or social process, and whether the sudden increase immediately following the birth of offspring is due to a release of that defense," he said.

Paffenbarger said women who experience a pregnancy-related mental illness are similar to women in the general population in terms of social and cultural variables and show no evidence of greater psychic stress before becoming pregnant. The variables include birthplace and residence, urban or rural; husband's occupation, and the birth of illegitimate children.

Collective bargaining negotiations for a new agreement between the Committee for the Recognition of Nursing Achievement (CRONA) and Stanford University Hospital are underway, both teams announced Tuesday, Jan. 26.

Both the Hospital and CRONA agreed to issue joint public statements as necessary during the course of negotiations which started Jan. 13. The current 20-month bargaining agreement expires Feb. 28.

The CRONA team is composed of chief negotiator and organization president Hedy Dumpel, R.N., J.D.; Patti Tharp, Alice Serbein, Sue Healy, Linda Stickles and Jan MacLachlan, all registered nurses.

Representing the Hospital are Priscilla Wheeler, staff counsel and the University's chief labor attorney, who will serve as chief spokesperson for the Hospital in the negotiations; Dan Robinson, assistant director of Personnel; Nancy Madsen, assistant Hospital director and associate director of Nursing; and two assistant directors of Nursing, Joyce Miller and Eileen O'Reardon.

CRONA represents about 1,200 registered nurses at SUH.

No further details on the negotiations were immediately available.

Nobel Laureate David Baltimore, Ph.D., a professor of microbiology at the Massachusetts Institute of Technology, will give the third John W. Cline Memorial Lecture, January 28 at Stanford Medical School.

Baltimore will discuss "The Transforming Gene of Abelson Murine Leukemia Virus," at 4 p.m. in Fairchild Auditorium. Baltimore will also visit with the faculty Jan. 28 and 29.

Organized by Dr. Saul Rosenberg, professor of medicine and radiology and chief of the Division of Oncology at Stanford, Thursday's seminar will be co-sponsored by the California Division of the American Cancer Society and the John W. Cline Memorial Lectureship Committee.

Dr. John Cline was an associate clinical professor of surgery at Stanford School of Medicine from 1929 to 1964. A native of Santa Rosa, California, he earned his M.D. at Harvard and practiced medicine in San Francisco. Cline was a past president of the American Cancer Society and the American Medical Association. He died in 1974.

The lecture named for Cline is a state-wide program which has supported the visits of prominent cancer researchers to major California medical schools. Previous lectures featured Dr. Jonathon Rhoades, at U.C. Davis, and Dr. R. Lee Clark, at the University of Southern California.

The upcoming seminar will be open to the public. There are no fees or registration required. For further information, call 497-5877.

Are diabetic patients really deficient in insulin?

Volunteers are sought to help answer this question by participating in research conducted by Dr. Gerald Reaven and associates at the Clinical Research Center of Stanford University Hospital.

Both male and female subjects are needed, of all ages. They should have a history of borderline, mild or moderate diabetes, or a family history of diabetes. They currently must not be on insulin therapy.

Participants will undergo, free of charge:

- evaluation of blood sugar and lipids (cholesterol, triglycerides);
- oral glucose tolerance tests and meal tolerance tests;
- routine health evaluation including liver and kidney function tests, cardiogram, chest X-ray, physical examination, and dietary evaluations;
- evaluation of diabetic management;
- short-term studies (two days with no hospitalization required).

Anyone interested or wishing further information should call Dr. George Liu, at 497-6054.

STANFORD—

Taking a newborn home for the first time usually means a big adjustment in lifestyle for any parents.

But when birth has been premature or otherwise complicated, leaving for home can be traumatic.

This, says Kathy Petersen, discharge planner of Stanford University Hospital's Intensive Care Nursery (ICN), is because parents there are used to having experienced personnel attend to their infant's needs during an extended stay in the Hospital. And they are also emotionally drained by the unexpected ICN experience itself.

Facing an environment where they alone are to be solely responsible for their baby—who may require continued medical care and equipment—is often frightening.

It was in recognition of the need to better help families make a smooth transition between ICN and home that Petersen's position was recently established at Stanford.

A physical therapist with a master's degree in early education, Petersen had worked with handicapped and developmentally delayed children and infants for twelve years in community agencies.

ICN-experienced infants, she says, are often different from other newborns in terms of needs and behavior patterns. They may have irregular or difficult sleeping and eating habits, for example. Parents must learn to adjust the plans they made before birth, ensuring optimal chances for their baby's healthy development at home.

While in the past physicians, nurses, and social workers have all pitched in as necessary, explains ICN clinical nurse coordinator Kathi Palange, a full-time staff member focusing on such issues and serving as a continued contact at the Hospital has "probably been needed for awhile."

The need has been especially clear since the ICN renovation was completed last April, she says, providing an increased bed capacity (which has been filled from the start) for more acutely ill newborns.

Also, Palange points out, someone like Petersen—who's been serving in the community these past several years—knows more first-hand about the various resources and services available than most hospital-based personnel.

"I'll spend a lot of time coordinating efforts with outside resources," predicts Petersen, "as well as augmenting the home care training offered in the Hospital."

-more-

Her role, she points out, will go hand in hand with that of ICN social worker Charlene Canger, who provides important support for families during the period of their infants' hospitalization.

Petersen's position, which began early this month, comprises a one-year pilot program, made possible through the efforts and generosity of a group called "Friends of Children needing Special Care."

Starting with one family of a cerebral palsied boy Petersen had been treating, the group grew to include four couples, all eager to help sponsor a discharge planning position in Stanford's ICN because of their concern for premature infants and their parents.

Petersen had approached SUH last April, promising to help develop such a program herself. Now that it exists, the donor group as well as the ICN staff hope to see it become a Hospital-funded service after the first year.

"The records we keep and our follow-up evaluations should prove that it's needed," says Palange.

Already, she says, Petersen has been involved in the discharge planning of several families—including a set of premature twins who will be going home soon, both on sleep apnea monitors.

To prepare themselves, the parents of the twins—who have been in the ICN for over a month—have "practiced" caring for them by staying overnight a couple of times in the Hospital's "Parent Room," especially designed for such purposes. Petersen's job, of course, includes facilitating such rehearsals.

Without a strict protocol to follow, Petersen will use intuition, experience, and suggestions from the staff in developing the present discharge program as well as guidelines for the future.

She stresses, overall, the importance of early intervention to help parents participate in their children's best development, and to prevent avoidable problems associated with birth-related disabilities.

(Editors: This story sent Business Wire Jan. 20)

STANFORD—

A 26-year-old native of Grand Island, Neb., who became terminally ill after suffering from pulmonary hypertension for five years, became Stanford's sixth heart-lung transplant Wednesday morning (Jan. 20) in a three-hour operation which began about 7:30 a.m.

The operation came within two weeks of encouraging followup examinations of Mary Gohlke, 46, who became Stanford's first heart-lung transplant patient March 9, and Charles Walker, 31, who received the second such operation here May 1, 1981.

Cardiologist Sharon Hunt said the heart and lungs of both patients were normal for persons of their age. She added that the results indicated "this is a viable procedure and offers the feasibility of returning the patient to a very normal lifestyle."

The vital signs of the latest patient, Nancy Lassen, were reported stable by Dr. Bruce A. Reitz, the cardiovascular surgeon who heads the heart-lung transplant team and has performed at all six surgeries.

Lassen was reported in critical condition, the standard designation for all heart-lung transplant patients within the first few days of the operation.

The patient was selected recently for the operation after doctors determined that her pulmonary hypertension would lead to certain death within six months. She began suffering from the disease at about age 21 during her first year of nursing school.

Despite her condition, which includes shortness of breath and lack of stamina, Lassen was able to become a professional nurse. She subsequently worked at Children's Hospital in Omaha, Neb., but about a year ago was forced to cutback to a part-time schedule after moving to Phoenix where one of four sisters, a radiology technician, lived. In October, she had to stop work altogether. She is single, and her parents live in Nebraska.

-more-

Her condition is similar to that of Gohlke, and Darlene Moore Mathern, who received the fifth heart-lung transplant at Stanford Dec. 1. Pulmonary hypertension, an incurable disease of unknown cause, results in high blood pressure in the pulmonary circuit. As pressure in the pulmonary arteries, servicing the lungs, increase, the right side of the heart has to work harder to deliver the proper amount of pressure. Eventually the heart becomes irreversibly damaged.

Consequently, the combined heart-lung transplant procedure offers the only current hope for such patients.

Four of the first five of Stanford's heart-lung transplant patients are reported doing well. One patient, Karen Wilson of Mill Valley, Calif., died several days after her July 28 surgery when scar tissue from previous open heart surgery resulted in excessive bleeding.

Only the most recent patient, Mathern, 37, remains hospitalized, although doctors report her progress as good. She is exercising regularly and frequently leaves the hospital on pass.

The first two patients, Walker and Gohlke have been judged fit to participate in any activities normally pursued by persons of their own age.

The earliest heart-lung transplants were performed in South Africa, Texas and New York between 1968 and 1971, but the longest survivor lived only 23 days.

The procedure was suspended worldwide until research disclosed that a new drug, Cyclosporin A, circumvented two previously formidable obstacles: the slow and imperfect healing of the windpipe and life threatening infections.

Reitz said recently that he hopes longevity statistics for heart-lung patients will match those for Stanford's 226 heart transplant patients, who now have nearly a three fourths chance of surviving more than a year. All candidates were selected only after doctors agreed they faced certain death within a year without the surgery.

Stanford's longest living heart transplant survivor is active and has lived more than 12 years since surgery.

STANFORD—

A new book, *NMR in Molecular Biology,* by Dr. Oleg Jardetzky and C. C. K. Roberts has been published by Academic Press (640 p.p., $59).

The book, a part of a molecular biology series, discusses the applications of the technique of nuclear magnetic resonance (NMR) to a wide variety of problems in molecular biology.

Included in the new volume is a review of the literature on NMR to the end of 1980 and work published in 1981. Among the chief topics presented are the basic principles of the method and critical reviews of its applications to the study of the structure and dynamics of proteins, nucleic acids, and membranes as well as some small molecules of biological interest.

The technique of nuclear magnetic resonance owes its existence to an important discovery made more than 30 years ago. In 1945, Dr. Felix Bloch, now professor of physics emeritus at Stanford, and Prof. E. M. Purcell of Harvard simultaneously discovered and described the phenomenon of NMR.

They were the first to observe that atomic nuclei have magnetic properties, or in other words that all the hydrogen atoms and certain of the carbon atoms in a molecule will respond to a magnetic field. When the two scientists dropped whole molecules into a strong magnetic field, they saw that these atoms would absorb certain frequencies of radio waves. Moreover, each atom in the molecule would give off its own distinct "signature." Thus, they could study the structures of molecules, such as enzymes, antibodies and other immensely complex proteins.

The authors of the new book, Dr. Jardetzky is professor of pharmacology and director of the Stanford Magnetic Resonance Laboratory, and Dr. Roberts is associated with the National Institute for Medical Research at the Ridgeway Mill Hill in London, England.

STANFORD—

The first nuclear magnetic resonance spectrometer in the United States, based on a persistent (stable) superconducting magnet, will be built for Stanford University under a contract with Japan Electron Optical Laboratories.

"The 600 MHz (Mega Herz) spectrometer will provide to the scientific community at Stanford the most powerful instrument of its kind," said Dr. Oleg Jardetzky, professor of pharmacology and director of the Stanford Magnetic Resonance Laboratory located in the Chemistry Building.

The new instrument is financed by a $660,000 grant from the National Institutes of Health (NIH). The laboratory, which operates as a national resource under guidelines from the Biotechnology Resources Program of the Division of Research Resources of NIH, is available to researchers from all over the country who want to explore various chemical, biological and medical problems.

A similarly powerful spectrometer, said Jardetsky, was constructed in 1979 at the Carnegie-Mellon University in Pittsburgh, Penn., but it is based on a non-persistent magnet, requiring frequent recharging.

Persistent magnets of such a high field and resolution were not technically feasible at the time, he added.

The 14T (Tesla) magnet—the heart of the high-resolution spectrometer—will be built under a subcontract by Oxford Instruments, Ltd., Oxford, England. The company is currently building the prototype magnet for Oxford University.

Delivery of the new spectrometer system at Stanford is scheduled for the spring of 1983, said Jardetzky.

The work of the Stanford Magnetic Resonance Laboratory is devoted to the study of biological structure and function, and the development of possible applications to medical diagnosis, Jardetzky explained.

The method of nuclear magnetic resonance spectroscopy, or NMR for short, makes it possible for researchers to pinpoint all the atoms in a complex protein molecule. Moreover, it allows them to observe exactly how the atoms move through space and time.

-more-

"There are many ways to look at matter and nature up close," he added. "There are conventional optical microscopes, powerful electron microscopes, X-ray diffraction methods and a whole family of spectrometers.

"The NMR spectrometer is one of the most powerful devices in that it allows scientists to 'look' at structures many times smaller than can be seen with even the best electron microscope."

For example, a scientist may label amino acids—the building blocks of proteins—with stable isotopes, and, from NMR spectra, chart changes in protein structure which result from the interaction with drugs or other chemical agents.

The studies are important in understanding disease—for instance, abnormally shaped proteins associated with hereditary disease.

The researcher receives information on molecules as they move through time. The NMR spectra can be blipped onto a screen every few seconds, and the memory of each spectrum is then stored in a computer.

Thus, a scientist can follow the changes of shapes and motions of molecules with the added dimension of time, Jardetzky said.

"We can infer many things about the dynamic movements of these molecules," Jardetzky said. "And we are in a position to develop a model of a protein as it is alive and working."

Other methods of looking at proteins, he said, require that molecules be frozen or otherwise "killed" for viewing. The NMR method, however, allows them to float freely in solution. They are biologically active.

The Stanford laboratory, Jardetzky said, previously pioneered in the development of a 360 MHz NMR spectrometer, which at the time of its installation in 1974 was the most powerful instrument available anywhere.

"Significant advances in our understanding of the structure and dynamics of proteins, nucleic acids and membranes have resulted from the experiments done on this spectrometer since that time," the scientist said.

Over the past two years, applications of NMR at the laboratory have also been extended to living systems, making measurements inside plant and animal cells without destroying, invading or otherwise disturbing the organism.

"The new instrument will allow much better resolution of spectral lines," Jardetzky added, "and therefore still more detailed examination of molecular structures and cell constituents than has been possible so far."

TO: Science and medical writers

The business side of genetic engineering, whose payoffs are at best still several years down the road, captures headlines galore. But many scientists believe the real revolution brought about by genetic research lies in the basic scientific and clinical advances on the non-commercial side.

A new issue of *The Healing Arts*, "The Golden Age of Genetics," describes some of the basic research now in progress in the laboratories of the Stanford University School of Medicine. It shows that, in spite of the immense advances in molecular biology research, there is still a lot more to be learned—and it shows how recombinant DNA techniques, on which genetic engineering is based, are helping.

For example, scientists only now have the tools at their disposal to study what causes living cells to trigger the process by which DNA copies itself and controls growth. Only now can they investigate precisely what makes bacteria become resistant to antibiotics, how cells "talk" to each other, or how bacteria use genetic "tricks" to make people sick.

These are among the topics discussed in "The Golden Age of Genetics." Copies of *The Healing Arts* are available on request, if not included with this notice.

STANFORD—

When a patient is cured of Hodgkin's lymphoma he has conquered the most dread disease—cancer—yet his emotional problems may have only just begun.

In resuming normal lives, recovered cancer patients face unique psychological and social challenges. Doctors, whose training focuses on the biology of cancer and the latest technology for its treatment, often don't know how to help ease their patients' emotional burdens.

Now researchers at Stanford University School of Medicine have launched a two-year study to help fill in the unknowns and smooth the road to full rehabilitation of cured cancer patients.

Among other goals, the Stanford researchers hope to find ways of predicting which cancer patients are at high risk for later emotional troubles, to learn how to help prevent the problems from developing, and then, to incorporate this knowledge into the regular training of young physicians.

The study, funded by a $148,524 grant from The Robert Wood Johnson Foundation of Princeton, New Jersey, is one of 23 new projects aimed at helping people impaired by disease, disorder or injury to conserve or more swiftly regain their ability to perform the tasks of everyday living, the Foundation announced this week.

Only 30 years ago, Hodgkin's disease was considered incurable—today, nearly 80 percent of Hodgkin's patients who receive proper treatment can expect near-to-normal lifespans, according to Dr. Richard Hoppe, assistant professor of radiology who heads the rehabilitation study project. Treatment generally includes radiation therapy, drug therapy, or a combination of the two, Hoppe says.

The radiation and drug treatments themselves occasionally have distressing side effects, which can include sterility, leukemia, inflammation of the heart or lungs and increased susceptibility to infection; since Hodgkin's disease most often strikes individuals in their 20s and 30s, the course of treatment and its impact on life decisions can be great, says Patricia Fobair, the clinical social worker who is assisting Hoppe as coordinator of the project.

"In behavioral terms these problems might be experienced as chronic anxiety, depression, difficulties in motivation and in initiation and development of careers, or problems in achieving intimate relationships," explains Fobair.

"One of the most difficult tasks for survivors is learning to live with the fear of recurrence of the cancer and a sense of uncertainty about the future," she adds.

But the few small studies already done to evaluate quality of life in cured cancer patients point to some encouraging signs, Fobair says.

First, "not every patient becomes a casualty," she says. About one-half the patients interviewed in one study were doing well medically and psychosocially, she reports.

-more-

Furthermore, certain factors may help predict which patients will be least successful in resuming satisfactory lives. This would help doctors or social workers single out these patients for special attention in the form of peer support, skills training or other professional psychological or vocational help.

"Negative outcomes are most often seen among patients who experience 'body damage' as a result of the malignancy or its treatment, those with poor social support, and among those patients whose background includes a history of psychosocial difficulties," Fobair says.

About 9,000 new cases of Hodgkin's disease are recognized every year in the United States; approximately 100 new patients come to Stanford each year for care.

In the last 20 years, 1,116 patients have been treated at Stanford and 922 are disease-free, says Hoppe. During the first few months of the study, many of these patients will be asked to participate in the study by providing information on how they view their mood, self-esteem, coping abilities, social functioning, social support network, body image, and to provide socio-demographic information.

The analysis of this information will help the researchers identify some of the most pressing problems faced by survivors of Hodgkin's disease and the critical times when these problems emerge. From these results, the researchers hope to develop effective criteria for screening patients to find those at highest risk for emotional difficulties.

During the next phase of the study new Hodgkin's patients will be screened and offered different treatment approaches, such as peer group meetings or self-help skills training, to find useful ways of minimizing future psychosocial trauma.

Finally, and perhaps most important in the long run for patients and doctors alike, says Fobair, doctors-in-training and medical students will be taught the new techniques, along with their established courses on radiation therapy and chemotherapy.

"These teaching sessions will be devoted to increasing physicians' knowledge of psychosocial aspects of the cancer experience, methods of early identification of individuals at high risk for problems, and resources available for referral," explains Fobair.

Other researchers who will participate in the rehabilitation project include Dr. Joan Bloom, an associate professor from the School of Public Health at the University of California, Berkeley; Dr. Henry Kaplan, Maureen Lyles D'Ambrogio professor of radiology at Stanford; Dr. David Spiegel, assistant professor of psychiatry and behavioral sciences; Dr. Bradley Efron, professor and chairman of the department of statistics; Dr. Richard Cox, in the division of radiation physics; Dr. J. William Worden. an associate professor of psychology from Harvard University; and Dr. Doug Graham, a resident in radiation therapy.

STANFORD—

For Angel Nunez, 31, and thousands of other paraplegics, the wrong seat cushion could mean tissue injury, expensive hospitalization, and being off work for months.

So Donna Politi, a clinical evaluation consultant for the Palo Alto Veterans Administration Medical Center, listens attentively when Nunez and about 100 other paraplegics talk about how they feel using a new blue foam cushion.

Nunez, of Honolulu, said the new cushion is by far the most comfortable he has tried since a paralyzing gunshot wound seven months ago.

Not all 100 men trying out the new cushion are unanimous in their praise, but Inder Perkash, professor of surgery at Stanford University and chief of the Palo Alto VA Spinal Cord Injury Service, believes that the unassuming blue foam device might benefit most of an estimated 500,000 paraplegics in the nation.

Perkash is the principal investigator in the project being developed under a VA grant.

The contoured cushion may appear too ordinary to be taken seriously at first glance as an important medical accomplishment. But the contours have been meticulously engineered during years of research so that pressure on the user's thigh and buttocks is minimized, and so that the patient is able to mantain proper posture without slipping.

The danger faced by paraplegics is debilitating sores caused by shear, the pressure on tissue between a bony point and any hard external surface, such as a chair. Perkash estimates that about 15 to 35 percent of paralyzed persons are rehospitalized because of sores, which if left untreated can lead to bone deterioration.

If seated continually in a position of poor posture, paralyzed persons all run the risk of spinal deformities.

Everyone is prone to such sores, but the natural response is to shift position every few minutes while sitting to distribute pressure more evenly. During sleep, we unconsciously shift position periodically.

Unfortunately, paraplegics have no sensation in their buttocks or thighs.

"There's no message from their nervous system telling them, 'Hey, move your tush,'" explained Politi. "That's why the design of a seat cushion is so vital."

-more-

The new cushion, called VASIO (Veteran's Administration Seating Interface Orthosis), has evolved through eight versions since the research project began in 1977. The cushion has been evaluated continually by the paraplegic volunteers who rated it on 10 subjective criteria, including comfort, length of sitting time and ease of transferring from the chair to another vehicle.

In addition, a pressure sensor placed between the buttocks and the cushion was used to determine weight distribution compared to both a theoretical ideal and to currently available seats.

Eventually the particular contours were chosen because they seemed to distribute weight most evenly for most volunteers. The material, a combination of high and low density foam, was selected for both comfort and therapeutic benefit.

Perkash said efforts are now being made with the Tumbleform Co., Dolgeville, N.Y. to market the cushion. He estimated the price would run $100, about half the price of a rubber inflated cushion which most of the volunteers had been using before receiving VASIO cushions.

The cushion does not provide complete protection from shears, and Perkash cautioned that paraplegics still need to consciously shift position—generally by pushing up on the wheelchair armrests—whenever possible. Therefore, Perkash said he has not tested the cushion on quadraplegics, who are totally immobilized. However, some informal trials have shown that VASIO seems to work better for them than other cushions, and he hopes eventually to refine the concept to the point where they will be able to sit for long periods in a chair free of shearing without having to move.

One of the paraplegic volunteers, John Winterholler, 65, of Lafayette, Calif., said after two weeks of testing the cushion that it was similar but not better than his rubber cushion in terms of comfort.

He also said that because the cushion was thicker, he was forced to sit higher off the ground. This, he added, made it harder to reach down and pick up objects or rest his feet on the ground.

"But I have some residual sensation, and so I don't think I'm completely typical of most people who would be using the chair."

However, after three weeks, Winterholler commented, "I'm beginning to like it. I think it's going to work out just fine."

Jim Griffith, 35, a former Army mess sergeant injured two years ago in a traffic accident, said the VASIO not only is more comfortable but has improved his posture and mobility.

Ted Perry, 23, who was paralyzed in an offduty accident seven months ago while serving with the Army in Germany, said he only had one minor complaint about the VASIO:

During fishing trips, the VASIO doesn't float as well as his previous rubber cushion, he said.

STANFORD—

Peter J. Levin, former executive director of Stanford University Hospital and associate vice president for medical affairs at Stanford, has accepted a deanship at the University of Oklahoma.

Levin, who was succeeded in November at SUH by Sheldon S. King, will serve as dean of the college of public health and professor of health administration at the university's College of Public Health in Oklahoma City. The appointment is effective immediately.

Levin came to SUH in April 1977 from New York City, where he was an associate commissioner in the city Department of Health.

During his more than four years as executive director at SUH, the hospital's modernization plan was developed and a critical nursing shortage was eliminated.

Levin, who holds a doctor of science (medical care and hospitals) from the John Hopkins School of Hygiene and Public Health, has also served as executive director of New Haven Health Care, Inc., and acting executive director of the Bronx Municipal Hospital Center, N.Y.

He has taught at Albert Einstein College of Medicine of New York University, as well as at Yale University.

He began his career in health management and teaching at the Public Health Service Indian Hospital at the Blackfeet Reservation, Browning, Mont.

STANFORD—

Carla J. Shatz, assistant professor of neurobiology, has received a $100,000 grant from The McKnight Foundation to continue her research into how and why nerves properly connect the eye with the brain.

"You might say we must 'use it or lose it.' The theory we're exploring is that the nerves regulating eyesight in newborn primates, including humans, won't make appropriate connections in the brain without normal use of the eye," Shatz said.

"In more formal terms, we're specifically testing the hypothesis that the onset of function occurs at the same time as the sorting out of nerve connections occurs.

The scientist is studying how nerve connections between the eye and the brain develop in cats before birth.

"There has been a lot of research showing that nerve connections in adult mammals are precisely organized. But before birth, the nerve endings don't always lead from the eye to the exact point on the brain where they are supposed to be.

"It's as if the nerve cells have all found the right city but need to locate the exact street address. "Later, usually about the time of birth, the connections tend to sort themselves out beautifully, so that nerves running from the eye to an inappropriate point disappear, allowing correctly placed nerves to flourish."

Although the sorting out process has been well documented, Shatz said that the reasons behind the change are not fully understood.

By studying cats before birth, Shatz is hopeful to learn how the process occurs and whether indeed it is related to function.

"We have some strong evidence from other sources that the use of an organ—in this case the eye—is a vital part of neurological development:

"For example, when a child is born with a cataract in one eye, the other good eye will tend to become strong at the expense of the afflicted eye. Even when the cataract is corrected by surgery, we find that the nerves in the diseased eye will not have developed properly.

"We hope that our study will help us understand show how one eye becomes dominate at the expense of the other eye."

The Minneapolis-based foundation offers about $9 million in various grants yearly. This was the first year of Neuroscience Development Awards, given to 14 persons. Shatz' grant will be given in three equal annual installments.

Shatz previously received grants from the March of Dimes Birth Defects Foundation, the Andrew W. Mellon Foundation of New York, and the National Eye Institute of the National Institute of Health.

She came to Stanford in 1978 after completing her Ph.D in neurobiology and serving as a postdoctoral fellow at Harvard University.

Statement from Dr. John T. Mehigan and Dr. Cornelius Olcott, IV, clinical assistant professors of surgery at Stanford University, attending physicians for 10-year-old Donald Priest:

"The patient underwent bilateral midcalf open amputations and appears to be a good prospect to later revise the amputations to closed below the knee amputations. Essentially, we are saying that within the next five to ten days, the patient will probably undergo a second amputation. We are optimistic that the operation will be closed below the knee, offering good prospects for later physical rehabilitation. (Retaining a functioning knee improves rehabilitation prospects).

"Despite the fantastic treatment provided at Fresno Valley Medical Center, Donny arrived here pretty sick. Sometime yesterday (Tuesday), a fever had occurred and it looked like infection had set in. His temperature reached 39 degrees centigrade (about 103½ f), and this indicated that surgery should be performed quickly. Since that time (about noon) his fever returned to normal and the threat to his life is only very modest at this moment.

"The operation this morning removed the gangrenous portions of the legs, and we left the wounds open to drain. We are waiting now to see the infection subside, and when this occurs, we will seriously consider the second operation, which will involve modifiying and closing the current wound. "If all goes well, we should have him fitted with artifical legs in four to six weeks. He's a pretty great kid. I told him he would be the bionic kid, and he just laughed and agreed."

How do oral contraceptives and physical exercise interact to control blood cholesterol levels in women?

Researchers at the Stanford Heart Disease Prevention Program are seeking women volunteers between the ages of 21 and 35 in the following categories to participate in a study addressing the question:

•using oral contraceptives, with a sedentary occupation and no regular physical exercise;

•not using oral contraceptives, with a sedentary occupation and no regular physical exercise.

Volunteers will make one visit to the Heart Disease Prevention Program facilities at 730 Welch Road, where staff will draw small blood samples, conduct a bicycle fitness test, and determine body density by underwater weighing.

Participants will receive detailed information on their blood cholesterol levels, percentage of body fat, and their maximum oxygen transport capability (a measure of physical fitness).

Those interested in volunteering should call Dan Merians at (415) 497-6254 for more information.

STANFORD—

In contrast to highly-publicized reports that 30 percent of the nation's federal Health Professions Student Loans fail to be repaid on schedule, Stanford Medical School's loan delinquency rate is only 5.8 percent.

This, says the School's financial aid administrator for the past three years, Droni Moo, means that about 19 former students are at least 120 days overdue in their repayment schedules.

The low delinquency rate at Stanford, say Moo and University Bursar Joseph Jedd, contrasts with the national average for medical schools, recently found to be 16 percent.

In an effort by Senator Charles H. Percy (R) of Illinois to introduce crack-down legislation concerning delinquent borrowers, it was discovered that about one-third of the nation's former medical students—many of whom now run successful private practices—are responsible for about $23 million worth of overdue loans.

Since their repayments are meant to be used by universities to finance new loans to present students, the problem manifests itself in tighter distribution budgets.

Stanford Medical School receives only 10 to 20 percent of what it asks for in new loan money each year from the government, says Moo. This, she says, is because of the general trend towards decreasing appropriation of funds for health professions education.

And the impact is worse with the major budget-cutting of the Reagan Administration. In fact, she predicts an advance of less than 10 percent from the government in the coming year. "I foresee in the near future having very few funds to loan out except what we get back as repayments."

She adds that recent press attention regarding the delinquency problem has affected both the attitudes and actions of Congress, whether or not the situation is fully understood in all its complexities.

Legislation being pushed by Percy includes reporting delinquent borrowers to commercial credit bureaus, as well as other measures to aid institutions in loan collection.

"I think his legislative efforts are fine," says Moo, "as long as schools which already have good track records are not penalized along with the rest."

She emphasizes the importance of having the administrator of the program, the Department of Health and Human Services (HHS), clarify policies and collection procedures more thoroughly. "We don't yet have clear directives on who is defined as delinquent." (It is unclear, for example, whether a student is delinquent after 90 or 120 days of non-payment.)

-more-

The HHS cutoff rate for acceptable delinquency at any school is five percent. Stanford, says Moo, is a bit over this rate simply because some students have failed to file the paperwork necessary to defer their loans. (Students are not required to begin paying back loans until they are completely finished with their training.)

At Stanford, the distribution of medical student loans is based solely on need. All who qualify, says Moo, do receive health professions loans, though sometimes in amounts smaller than the ideal.

"It's obvious that what past medical students are doing does affect present and future medical students."

The profile of the delinquent borrower is hard to draw, says Jedd. "Throughout the University, we find that some of our graduates who earn only $12,000 a year are prompt, while some who earn $30,000 are not." He indicates, however, that the number of successful professionals who totally ignore their past college loans at Stanford is very small.

He says 6.7 percent, or $1,700,000, of the total outstanding loans at Stanford are in the health professions area.

In the academic year ending Aug. 31, 1981, only about 33 new HHS loans were issued to Stanford medical students. The Bursar's office keeps very accurate data in the form of a file on every student who receives a loan.

Stanford's collection efforts have been largely successful, says Jedd, because of the vigor and diligence of its policies. A well-staffed professional collection group and an in-house computerized billing service are important components. When necessary, collection agencies are used and court action may be authorized.

"Also," he adds, "Stanford is a prestigious university. It is difficult to get in, and once in students are less likely to drop out." In fact, he explains, some of the delinquent borrowers included in the flaunted national statistics are people who have left school, never attaining the degrees they originally aspired to.

"Or sometimes," he continues, "people don't pay back the *amount* they're supposed to at each installment, but they do pay *something* regularly. And they pay back the full amount they owe eventually."

Asked about medical students' performance compared to other groups on campus, Jedd reports that those receiving health professions loans have behaved similarly to others in terms of repayment.

STANFORD—

Dr. Kenneth Melmon, chairman of the Stanford University Department of Medicine, sits on a brightly lit stool in front of a busy nursing station at Stanford University Hospital.

He's dispensing medical advice, but not to patients. He's filming a segment in a new public television series, **Health Notes,** which began airing on KQED-TV (Channel 9 in San Francisco) in December.

Although medical programs have been produced before, the new series is unusual because the planning intimately involves three eminent doctors from two major medical centers collaborating to produce advice on sensitive and previously little explored topics.

"These are not a series of simple health tips," said Melmon. "What we're dealing with here are controversial health care issues for a bright but nonmedical audience—the sort which people are reluctant to talk about because of their complexity, or because they may challenge authoritarian physicians or 'traditional' medical practices.

"We're dealing with the sort of issues which will allow people to ask their doctors more intelligent questions and become an integral part of their own treatment."

The programs currently are being produced in a three to five minute format, although Melmon hopes they will create enough interest so that funding will someday be available to explore more issues, in greater length and depth.

" . . . We felt institutionally that we have an obligation to the public to get involved in this sort of thing," Melmon added.

Each of the series' 10 parts, scheduled to air through October, 1982, under sponsorship of the Robert A. McNeil Foundation and the Henry J. Kaiser Family Foundation grant, will explore a different topic. The episodes are being sandwiched between regularly scheduled programs and are repeated several times.

Coordinating the series is Dr. David Watts, associate professor of medicine and chief of the gastroenterology clinic at the University of California, San Francisco. He is working closely with Melmon and Lloyd H. Smith, chairman of the Department of Medicine at UC San Francisco.

Drug Interactions was the subject of the episode which Melmon filmed recently.

"There are many drugs which when given in combination produce uncertain results. No one really knows what will happen chemically to the patient when various medications are mixed in new ways," Melmon explained.

"While often the drug interaction is essential to save the life of a patient, an educated public should be aware that prescribing multiple medication is a complex task."

Among other topics scheduled for the series is *Sunshine and What it Does to our Skin* (premiering Jan. 6 at 7:55 p.m.). The series began with a precis of what it means to a patient to be told that he has high serum cholesterol, and how this contributes to arteriosclerosis.

Each episode is filmed in a medical setting intended to augment the expert's verbal explanation.

But Watt said the emphasis is on factual information.

"It's important that the public has access to good information. All too often medical information is sensational, overdramatized, and prematurely definitive.

"New drugs, for example, are presented as if they were coming out tomorrow, and will cure without consequence. The side effects are not mentioned and information is often distorted. It needs to be balanced."

"Welcome Santa Cruz Folks," reads the sign on the door. "This may not be home, but at least it's dry."

That's the message greeting kidney diaylsis patients who are unable to obtain vital dialysis therapy in storm-damaged Santa Cruz and have been coming to Stanford Medical Center's Hemodialysis Unit to obtain the life-saving treatments.

At least 60 chronic dialysis patients who normally receive their blood cleaning treatments two to three times per week at Santa Cruz Community Dialysis Center were forced to obtain dialysis elsewhere when their unit shut down Tuesday. Lost telephone lines, intermittent electrical power, and an inadequate supply of water caused by broken mains forced the closure, explained Pam Simmons, clinical nursing coordinator for the Stanford Center.

In order to help out, Stanford has called in nurses and technicians to work overtime and additional dialysis machines have been moved into the unit in order to accomodate 16 or more of the Santa Cruz patients until their local dialysis unit resumes operation, said Dr. Robert Swenson, Medical Director of the Stanford Hemodialysis Unit.

Staff at the Santa Cruz Center have done "an excellent job in placing their patients at several dialysis units in the area." said Simmons, noting that Frank Lacy, the Santa Cruz Center's administrator, and Medical Director Dr. David Gelbart, personally drove miles out of the way in order to phone their patients to let them know where to go for treatment, and to deliver medical records to the other units helping out in the emergency.

(more)

In addition to the 16 or more patients added to the schedule at Stanford Medical Center, Valley Medical Center and Satellite Dialysis, Inc., have each taken in several patients, Watsonville Hospital and Dominican Hospital in Santa Cruz, working on emergency power, also made room for some of the 60 displaced dialysis patients from the Santa Cruz Unit, Simmons said.

A few of the patients were scared and nervous about coming to a new unit, said Simmons, particularly those who were older or who had never been out of Santa Cruz for their dialysis treatments. But several patients interviewed were philosophical about the disruption to their routine. "It's a bit inconvenient having to drive over the mountains to get here," said one man from Aptos, "but I feel terribly lucky compared to the people who have lost their relatives or their homes."

The extra patient load, which will continue indefinitely, is being handled in three shifts at Stanford, running from 7 A.M. until 12:30 A.M., with eight patients per shift, said Simmons.

It marks the second time in the last six months that the Stanford Dialysis Unit has taken on extra patients in an emergency. In August last year, patients from El Camino Hospital had to obtain dialysis elsewhere when their facility closed for several days because of contamination in the water.

EDITORS: Advance for release A.M. Tuesday, January 5, 1982

EDITORS: Details follow asterisks. The following release coincides with publication of the December issue of the *Proceedings of the National Academcy of Sciences*. Photos available on request of Dr. Kornberg and his colleagues and of DNA replication proceeding bidirectionally from the replication origin on a plasmid.

STANFORD—

Biochemists at Stanford University School of Medicine have succeeded for the first time in creating a test tube system with all the ingredients necessary to initiate a round of synthesis of the DNA of a bacterial chromosome.

The work is considered important because it is a first step towards discovering how cells control the frequency of DNA replication initiation, a significant event in controlling the overall rate of cell division and growth, the researchers said.

Since the structure of DNA was discovered nearly 30 years ago scientists have unraveled many mysteries of how the molecule replicates to produce identical copies of itself for the next generation of cells. But one crucial problem has remained obscure: how does a cycle of DNA synthesis begin?

Through their new enzyme system, finally the resolution and analysis of factors that control initiation of a chromosome cycle should become accessible, the researchers predicted.

The feat was accomplished in the laboratory of biochemistry professor Dr. Arthur Kornberg, a Nobel laureate who in 1959 created synthetic DNA for the first time, and in 1967 reported the first successful test tube synthesis of DNA that was demonstrated to be biologically active.

Kornberg called the latest achievement "a milestone" in his laboratory's continuing efforts to understand the complex biochemical basis of DNA replication.

His colleagues on the project are Robert S. Fuller, a Ph.D. candidate in biochemistry and Jon M. Kaguni, a biochemistry postdoctoral fellow. A report of their work was published in the December issue of the *Proceedings of the National Academy of Sciences*.

The beginning of DNA synthesis is a key process in the life of a cell, Kornberg explained, because the point at which chromosome replication gets started is the point of commitment, determining whether or not a cell will double its DNA and therefore, whether or not it will reproduce.

Finding how cells control their growth rate could solve some long-outstanding and fundamental questions, such as how cells become transformed, or cancerous. (Rapid, continuous and uncontrolled growth is a hallmark of cancer.)

Understanding the control of DNA replication initation could also explain why embryonic cells synthesize DNA continually and adult cells remain relatively quiescent, Kornberg said.

But at this stage in the research, it's far too early to speculate about what will be found, Kornberg stressed. "If you ask what we can say about major questions of control of growth and cancer at this time, the answer is very little," he said.

"Not only are we not working with animal cells where these questions have been posed, but comparable questions with regard to simpler bacterial cells have not been broached. We don't anticipate any answers until we know a lot more about the details of the system," Kornberg added.

-more-

2-2-2 Kornberg and his colleagues carried out their work with bacterial plasmids—small circular pieces of DNA independent of the main bacterial chromosome—that were genetically engineered to include the segment of the main chromosome at which DNA synthesis always begins, the so-called origin.

The researchers grew colonies of *Escherichia coli* cells that harbored the origin-containing plasmid, called pSY317. Then they broke open, or lysed, the cells and collected the resulting fluid that was brimming with cell components. But in this rich cell soup, they found that no DNA synthesis was initiated.

"It may not seem reasonable to think that if you start with something inactive, you can then obtain a fraction from it that is active," said Kornberg, "but that's what was done."

By adding just the right amount of ammonium sulfate, a salt that precipitates proteins, the researchers came up with an active fraction.

The amount of salt added is crucial, explained Kornberg—if just a little more is added, an inactive fraction is obtained. By adding the salt, which precipitates certain proteins and other cell components, ingredients necessary for DNA initiation were concentrated or something was excluded that had inhibited initation in the total extract, Kornberg suggested.

The quest to find an active fraction of the bacterial soup in which DNA synthesis could be initiated was an arduous one. "We sought this system for many years," recalled Kornberg, "without success. Many other laboratories around the world were also working very hard on this problem. However, when we found it, the reaction turned out to be much more clear and powerful than we anticipated.

"Initiation of DNA synthesis is actually a rare event—it happens only once in the lifetime of the cell. We are astonished and pleased by the high level of synthesis we have found."

The first attempts to find a system for studying how DNA synthesis begins were carried out using purified proteins known to be involved in the replication of viral DNA, and involved looking for additional factors that would stimulate replication. Only after these attempts proved fruitless did Kornberg's group attempt to extract active fractions from solutions of disrupted bacteria.

Kornberg cites graduate student Fuller's talent and perseverance as "important ingredients" in the lab's latest accomplishment, one that had proved so elusive over many years of hard work.

"Why it took so long to find this DNA synthesis initation system will be answered, in part, by finding out precisely what's in the system that is exacting and irreplaceable," Kornberg said.

"As we sort out the components of this machine, we will learn which elements were absent or defective in previous preparations as compared to the present one. Probably most of our previous failures came about because we were missing several substances in optimal levels. Now we will analyze very precisley, quantitatively, what substances are required.

"The basic processes of synthesizing DNA chains, transcription of this genetic material into the RNA language, and translation of the genetic code into protein are essentially identical in bacteria, plants, animals and humans," Kornberg said.

"For that reason, we have confidence and optimism that understanding these basic processes in bacteria, where research can be done more precisely and easily, will give reliable insights into how these processes occur in higher levels of organisms.

"That there is a universal use of basic biochemical patterns throughout nature warrants our confidence that regulation of these processes, when understood in one system, will become far easier to understand in all systems.

"It is my conviction that the most important elements in understanding the process of chromosome replication initiation will come through knowing its biochemistry," Kornberg added.

The research was supported in part by grants from the National Institutes of Health and the National Science Foundation and by fellowships from the American Cancer Society and the Damon Runyon—Walter Winchell Cancer Fund.

-more-

Placing the *E. coli* origin on a plasmid (using recombinant DNA techniques) contributed significantly to the recent success, explained Kornberg. The origin-containing plasmid used in these experiments was first constructed in Japan by biochemist Dr. Seiichi Yasuda, who later worked in Kornberg's laboratory during the years of 1978-79.

Inserting the origin sequence in a plasmid was really a strategy to enrich for the origin region, which is otherwise a relatively short portion of the *E. coli* genome, occurring just once per chromosome molecule.

It's probably impossible, said Kornberg, using even the most sophisticated techniques, to extract the entire *E. coli* chromosome intact from an *E. coli* cell; it's an intricately coiled string of approximately four million nucleotide base pairs. But a plasmid is a more manageable molecule a few thousand nucleotides long (approximately one-thousandth the size of a chromosome) and it will remain intact when the bacterial cell is broken open.

If the origin were not embedded in a plasmid, trying to locate the sequence, which is only 245 base pairs long (or 1/16,000 the length of the chromosome) would be like trying to find the "needle" in a "haystack" of fragmented pieces from the cell, Kornberg mused. "By placing the origin on the much shorter plasmid, we enriched for it approximately 400-fold," he remarked. "What's more," he continued, "because a plasmid can replicate independently in the bacterial cell, we can obtain as many as 100 copies of the origin, instead of just one, from each bacterial cell."

The new system behaves much like the DNA replication initiating machinery inside an *E. coli* l. This gives the researchers confidence that their test tube system is physiologically genuine, that it represents the intiation process as it is actually carried out in living cells. For instance, it is knocked out by the same poisons that are capable of blocking initiation in living bacterial cells, and its activity requires the presence of certain genes and enzymes already known to be required for initiation.

Another expectation of a genuine DNA synthesis initiation system is that it would start replication going in both directions from the point of origin—this is known to be the case in *E. coli*, Kornberg said. By examining with the electron microscope origin-containing plasmids from the test-tube system, the researchers confirmed that replication did proceed bidirectionally. This was an added proof that the system was physiologically relevant, they reported.

The eventual aim of this research, Kornberg said, is to characterize the genes and the proteins involved in carrying out and controlling initiation of DNA synthesis. Most likely, several proteins are required, and in fact, some of these are already known. Others await discovery.

And although the 245-nucleotide base pair origin sequence enables replication to begin on the plasmid, "adjacent sequences may be important for more complex behavior expected of the *E. coli* chromosome," Kornberg and his colleagues suggested. Just how the adjacent sequences play such a modulating role will be a focus of study using the new system, they said.

"Ultimately, the exploitation of this system should allow a direct biochemical approach to the regulation of replication," the researchers said. "The availability of an authentic system for the replication of the *E. coli* chromosomal origin should allow the isolation of those factors as well as the understanding of those processes which control the frequency of origin-initiation and couple the rate of chromosomal lication to that of the cell as a whole."

STANFORD—

A Tuesday noon lecture series on *Women and Health*, sponsored by Stanford Medical School's Division of Family Medicine, will begin Jan. 5.

All lectures, open to the public without charge, will take place in room M106 in the School of Medicine. The presentations include:

- **Jan. 5—Strategies for Life Enrichment**—with Mary Ann Tyson, Ph.D., a clinical psychologist;
- **Jan. 12—Exogenous Hormones and Women's Health**—with Jane Zones, Ph.D., a public health sociologist and researcher;
- **Jan. 19—Self Care for Women in Clinical Practice**—with Susan Baldi, R.N., M.D., health consultant;
- **Jan. 26—Women and Health Policy in the U.S.**—with Jane Zones, Ph.D.;
- **Feb. 2—Mothers and Children: Seeking Health in an Unhealthy World**—with Julie Olsen Edwards, director of the Department of Early Childhood and Family Life Education, Cabrillo Community College;
- **Feb. 9—Holistic Spirituality and Well Being**—with Alla Bozarth-Campbell, an Episcopal priest, gestalt therapist, and feminist poet;
- **Feb. 16—The Health of Older Women**—with Mary Averill, M.D., a fellow in geriatric medicine, Palo Alto Veterans Administration Hospital;
- **Feb. 23—When the Doctor is a "Lady": power, status and gender in physician-patient relationships**—with Candace West, Ph.D., assistant professor of sociology, U.C. Santa Cruz;
- **March 2—Women and Sexuality in Medicine**—with Judith Martin, M.D., Division of Family Medicine, Stanford.

The Division of Family Medicine is part of the Department of Family, Community and Preventive Medicine at Stanford. The lecture series, designed to address women's health issues not ordinarily included in medical education, may be taken for academic credit by medical and other Stanford students.

A discussion group with case presentations will be held for enrolled students following each lecture, from 1:15 till 2 p.m., with speaker Marita Grudzen, health care consultant, and Dr. Judith Martin, both from the Division of Family Medicine.

The course, says Martin, though not comprehensive, aims to provide a holistic and interdisciplinary approach to women's well-being.

For further information, call 497-7874 or 497-6431.

STANFORD—

Seven assistant professors at the Stanford University School of Medicine are recent recipients of Biomedical Research Support Grant awards, sponsored by the National Institutes of Health.

Their names and projects follow:

Jeffrey Sklar, M.D., Ph.D., of the Department of Pathology, is studying "*In Vivo* transcription of human globin genes cloned in eukaryotic DNA vectors."

Peter Parham, Ph.D., of the Department of Structural Biology, is conducting an "Investigation of the immunological roles of coated vesicles, their assembly and biosynthesis."

Howard Schulman, Ph.D., of the Department of Pharmacology, is studying "Calcium- and calmodulin-dependent protein kinases."

Arnold Kriegstein, M.D., Ph.D., of the Department of Neurology, is studying "Long-term neuropathological changes in an animal model of febrile convulsion."

Diana F. Guthaner, M.D., of the Department of Radiology (Division of Diagnostic Radiology), is studying the "Significance of errors in quantitative cardiovascular CT."

Robert V. Rouse, M.D., of the Department of Pathology, is studying "*In Situ* antigen specific events in the immune response."

Bruce G. Wallace, Ph.D., of the Department of Neurobiology, is studying the "Identification of factors mediating synapse formation."

A faculty committee headed by Dr. Eric Shooter, professor and chairman of the Department of Neurobiology, selects the award recipients at Stanford each year.

The purpose of the grant is to assist young scientists in funding basic and clinical investigations.

LOW CALORIE DIETS AND HEART ATTACKS: A WARNING

STANFORD—

Persons on diets of 800 kcals or less per day may be endangering their health even if under a doctor's supervision, say both a physician and a dietician at Stanford University Medical Center.

"It is certainly sound advice for persons to work with their physician when starting a diet. But extremely low calorie diets may cause a breakdown in structural protein, including heart tissue," said Peter Rudd, assistant professor of medicine.

"With a breakdown in heart tissue comes a risk of cardiac problems. These can occur suddenly and without warning. Even if a patient is hospitalized and constantly monitored, heart problems may still occur. Some are easily corrected, but others could be fatal," said Rudd, an internal medicine specialist.

Rudd and Stanford University Hospital (SUH) registered dietitian Jane Woeckener were interviewed separately in the wake of public interest triggered by the death of a Bay Area woman who reputedly adhered to a low calorie diet and by articles offering reassurances about various diet plans.

"There are no easy answers when it comes to dieting," said Woeckener, who serves as assistant director of dietetics at SUH. "But the safe and sensible way to lose weight involves eating a wide variety of low calorie foods from the basic four food groups (dairy, meat, fruits/vegetables, breads/cereals) and planning a slow, steady weight loss of about two pounds per week.

"Diets below 1,200 kcals for women and 1,500 kcals for men are generally not recommended because they almost always are lacking in important nutrients needed to meet minimum Recommended Dietary Allowances (RDAs) and to maintain health. (Kcal is short for kilocalorie and is the commonly accepted measurement of the energy value of food.)

"Behavior modification and changing the attitudes and habits which lead to being overweight in the first place are crucial components of weight loss. Crash diets with temporary results do not significantly lower the risks associated with obesity," Woeckener added.

Both Woeckener and Rudd cited recent studies suggesting that diets of fewer than 800 kcals per day are potentially dangerous. These studies, Rudd noted, examined several different nutritional regimens. The number of calories and variety of components appeared to be more important than the specific content of the diet, he said.

-more-

Woeckener and Rudd said that an extremely low calorie diet may be desirable only when someone is so obese that the risk of sudden death is high unless weight loss begins quickly.

"In these circumstances, the patient frequently is already hospitalized. Close observation will not eliminate the risk of sudden death while rapidly losing weight but would at least permit health professionals to respond quickly to a cardiac arrest," Rudd said.

He added that the heart is especially vulnerable to damage on a low calorie diet, even if protein is its main component. The addition of modest amounts of carbohydrates may reduce breakdown of the body's structural protein and may help protect the heart.

"But there have been reports of lowered potassium, calcium and magnesium, which could make irregular heart rhythm more likely. These electrolytes (blood minerals) are necessary, and they are best provided within the context of a well balanced diet," he added.

Among the studies cited by Rudd and Woeckener was one published in the April 1981 edition of *The American Journal of Clinical Nutrition*. Authors included Harold E. Sours, M.D., formerly of the Bureau of Epidemiology of the Center for Disease Control in Atlanta, and Victor P. Frattali, deputy director of the division of nutrition of the Food and Drug Administration, which currently is examining low calorie diets.

The article studied 17 individuals who died of heart attacks suddenly after long periods on very low calorie diets, consisting entirely or primarily of protein.

"The deaths appeared to be independent of type of medical supervision received during the diet, daily dosage of potassium supplementation and biological quality of the protein product used," the authors said. The 17 individuals had been on diets of about 300 to 400 kcals per day.

"We conclude," the article stated, "that use of very low calorie weight reduction regimens should be curtailed until further studies determine what modifications if any can insure their safety."

Contacted in Washington, Frattali said the article represented the research of himself and colleagues and did not indicate an official agency endorsement or warning. Officially "we're trying to keep ourselves informed in regard to low calorie diets," he said.

On Dec. 30, the FDA issued a public statement that diets under 400 kcals per day "are physiologically unsound regardless of their overall nutrient composition.

"FDA believes their use should be considered experimental and patients should have full knowledge of the risks, and undertake the diet only with proper medical supervision."

Diets under 800 kcals per day should be used only under proper medical supervision, the FDA said.

(Editors: The Medical Center News Bureau has available for the news media a packet of recent articles, including the Sours/Frattali piece, which will be mailed on request.

FIGHTING GONORRHEA: GENETIC ENGINEERING PROVIDES CLUES

STANFORD—

Stanford microbiologists are using genetic engineering techniques in an attempt to "pull the teeth" of the organism that triggers gonorrhea.

By manipulating the genes of gonococcus bacteria, the scientists have, for the first time, found a way to test an enzyme long suspected to be a weapon the bacteria use to produce the malady.

"If the enzyme turns out to be as important as we think it may be, it could be useful in constructing new ways to provide protection against gonorrhea," said Stanley Falkow, chairman of Stanford's department of medical microbiology.

Knowledge about the enzyme may lead to a vaccine or similar combatant against gonorrhea, Falkow said.

A major obstacle to creating a useful gonorrhea vaccine has been the gonococcus bacterium's ability to disguise itself, said Falkow.

Most bacteria wear a membrane coat that is studded with protein tags. Cells in the human immune system use these tags to identify the foreign bacteria, which they then destroy.

But the gonococcus can mutate and subtly change the configuration of its proteins, effectively camouflaging itself against the body's defenses.

"What you would like to do with an organism that can change its face like that is pull its teeth so that it can't cause an infection," Falkow said. "In other words, it could still multiply in the body, but not cause tissue damage."

The "tooth" in the case of gonorrhea may be an enzyme, called "IgA1 protease," that Falkow and a graduate student, J. Michael Koomey, have studied.

The bacterium uses the enzyme as a chemical cleaver that snips in two the normal antibodies a healthy person makes to fight off infection.

In response to an increasing number of invading bacteria, the human body produces more antibody. In turn, the bacteria produce more enzyme to destroy the antibody. The infected person loses the battle as he develops the genital sores and sometimes serious complications associated with gonorrhea.

-more-

Koomey and Falkow have identified the gene that is responsible for "telling" the bacteria how and when to produce the enzyme. Through a series of steps, described in the December *Proceedings of the National Academy of Sciences*, the scientists have been able to eliminate that single gene from the bacteria, creating an organism that is like gonococcus in every way, except that it can't make the critical enzyme.

The "impotent" organism now serves as a research tool in understanding the role of the enzyme in causing disease.

Normally, the next step in research would be to compare the responses of laboratory animals injected with either gonococcus or the engineered bacteria. But the crucial enzyme destroys only one specific human antibody, which is not present in animals.

This specificity makes the usual testing of the virulence of the bacteria in rodents and primates impractical, Falkow said, and has slowed research.

"If we can prove that the enzyme plays a role in disease, there are research groups interested in carrying the work a step further, to determine whether or not the engineered bacteria could be useful in providing protection against disease," Falkow said.

Although penicillin and its derivatives can effectively stop most acute bouts of gonorrhea, the antibiotics are only a temporary solution to the sexually transmitted disease, he added. Already, virulent strains of the bacteria have evolved that are resistant to penicillin.

"Another important reason we're interested in this particular enzyme is that it is also found in several organisms that cause meningitis (a dangerous infection of the membranes that surround the brain and spinal chord)." In contrast to gonorrhea, meningitis is not easily treated with antibiotics and is often fatal.

"The three major forms of bacterial meningitis all probably have this enzymatic strategy," Falkow said. "So we aren't just addressing the problem of gonorrhea, but also the more general question of the strategies bacteria use to cause disease.

"From the 1940s through the '60s, it was usually felt that through the use of antibiotics, infectious diseases caused by bacteria would be conquered, that we'd simply be able to treat them," Falkow said. "But through the advent of resistance, it became apparent that this was not going to be possible in many cases.

"There's another fundamental flaw in antibiotics," he added. "You have to wait for someone to get ill, and the whole basis of medicine really should be preventative."

STANFORD-THE NEGOTIATING TEAM REPRESENTING THE COMMITTEE FOR THE RECOGNITION OF NURSING ACHIEVEMENT (CRONA) ISSUED ON FRIDAY NOTICE OF INTENT TO STRIKE STANFORD UNIVERSITY HOSPITAL EFFECTIVE AT 12:01 A.M. MARCH 9 UNLESS DISAGREEMENTS LEADING TO A NEW LABOR CONTRACT ARE RESOLVED BY THEN.

THE NOTICE WAS DELIVERED BY THE UNION TO THE HOSPITAL NEGOTIATING TEAM HEADED BY PRISCILLA WHEELER, STAFF COUNSEL AND THE UNIVERSITY'S CHIEF LABOR ATTORNEY.

NO NEGOTIATIONS WERE SCHEDULED DURING THE WEEKEND, WHEELER SAID.

BECAUSE OF THE POSSIBILITY OF A STRIKE, THE PATIENT ADMITTING SERVICES DEPARTMENT HAS CANCELLED 13 OF 52 ADMISSIONS SCHEDULED FOR SATURDAY AND SUNDAY.

SHELDON KING, EXECUTIVE VICE PRESIDENT AND DIRECTOR OF THE HOSPITAL, SAID IN A STATEMENT, "WE ARE MAKING PLANS TO ENSURE THAT OUR CRITICALLY ILL PATIENTS WILL BE COMPLETELY CARED FOR. WE ARE CERTAIN THAT OUR NURSES WILL RECOGNIZE THE RESPONSIBILITY TO PROVIDE THIS SERVICE AS THEY HAVE IN THE PAST."

"IN THE EVENT OF A STRIKE, WE ARE CERTAIN THAT STANFORD UNIVERSITY HOSPITAL WILL PROVIDE THE SAME STANDARD OF EXCELLENT CARE WE ALWAYS HAVE, ALBEIT FOR A SMALLER NUMBER OF PATIENTS, THOSE WHO TRULY NEED IMMEDIATE CARE."

A 20-MONTH CONTRACT IS SET TO EXPIRE AT MIDNIGHT SUNDAY. TALKS HAVE BEEN UNDERWAY REGULARLY BETWEEN THE HOSPITAL AND CRONA FOR ABOUT A MONTH.

THE CONTRACT DISAGREEMENT CENTERED ON A VARIETY OF ISSUES INCLUDING THE COMPENSATION PACKAGE, WHEELER SAID. DETAILS WERE NOT IMMEDIATELY RELEASED PENDING FURTHER DISCUSSIONS BETWEEN THE HOSPITAL AND UNION.

CRONA REPRESENTS THE APPROXIMATELY 1,200 NON-SUPERVISORY REGISTERED NURSES AT THE 663-BED HOSPITAL.

(EDITORS: PRISCILLA WHEELER MAY BE CONTACTED DIRECTLY AT (415) 497-3628, OR AT HOME (415) 964-2418.

MEETING TO DISCUSS ACADEMIA-INDUSTRY RELATIONS

Science writers: The meeting described below will be closed to the press. However, if any agreement on principles to guide future academia-industry relationships is reached, we will make the results public as promptly as possible. It should be noted that any principles agreed upon at this meeting will be suggestions only to assist the universities involved in developing future policies in consultation with their faculties. If you are interested in being notified of the time and place of any follow up announcements, call my office (415) 497-6911.

STANFORD—

The presidents of five leading research universities will meet with their counterparts of several high technology firms as well as academic scientists March 25 through 27 to consider possible guidelines for the complex relationships that have sprung up between industry and academe.

The invitational meeting, funded by a grant from the Henry J. Kaiser Family Foundation of Menlo Park, will be at Pajaro Dunes, on the Monterey Peninsula.

Among the issues on the agenda: Should universities seek to return value from research developments to nurture the research enterprise and if so under what constraints? Should all research agreements between universities and companies be made public? Should universities aggressively patent and license faculty inventions? What should be the guidelines for universities holding stock in companies owned by faculty members? What are the consequences of industry-supported programs to the free exchange of knowledge and to the training of graduate students? How can the traditions of open research be preserved without forfeiting property rights necessary for companies to make commercial use of the research results? Are new conflict of interest rules needed?

"The main business of the meeting," said Stanford public affairs vice president Robert Rosenzweig, "will be to see if agreement can be found on a set of principles that might guide the growth of biotechnology as that industry interacts with universities."

Rosenzweig added that any agreement reached at the meeting will be made public.

The idea for such a high-level meeting was first suggested by Stanford University President Donald Kennedy in a speech at the University of Pennsylvania a year ago.

Kennedy, a former commissioner of the Food and Drug Administration and a member of the National Academy of Sciences, had expressed concern about the increasing interactions between academic scientists and industry, particularly in the field of gene-splicing, and their potential for subverting academic missions.

While universities need more interaction with industry, Kennedy said, "we need it on thoughtfully structured terms."

-more-

Rosenzweig said the five university presidents who organized the meeting have both experience and strong interest in national research policy. In addition, each has important reasons for making this matter a high priority in the development of policies for his own institution.

"They made a commitment to participate actively and developed the format of the meeting and list of attendees," he explained.

The university presidents are Derek Bok, Harvard; Marvin Goldberger, California Institute of Technology; Paul Gray, Massachusetts Institute of Technology; Donald Kennedy, Stanford University; and David Saxon, president of the University of California system.

The industry corporate executives are Arnold O. Beckman, Beckman Instruments, Inc.; Albert Bowers, Syntex Corp.; Ronald Cape, Cetus Corp.; Robert A. Charpie, Cabot Corp.; Samuel Eletr, Applied Biosystems, Inc.; David I. Kosowsky, Damon Corp.; Coleman Mokler, Gillette Corp.; Cornelius W. Pettinga, Eli Lilly and Co.; William Simeral, E. I. Dupont de Nemours, Inc.; and Robert Swanson, Genentech.

Faculty attendees and their institutions are Frederick Anson, professor of chemistry, and Norman Davidson, professor of chemistry, Cal Tech; David Hamburg, professor of health policy, Henry Rosovsky, dean of the College of Arts and Sciences, and Daniel C. Tosteson, dean of the School of Medicine, Harvard; Michael L. Dertouzos, professor of electrical engineering and computer science, and Phillip A. Sharp, professor of biology, MIT; Charles Yanofsky, professor of biological sciences, and Channing Robertson, professor of chemical engineering, Stanford; Paul Boyer, director, Molecular Biology Institute, UCLA; Julius Krevans, chancellor-designate, and William Rutter, professor of biochemistry and biophysics, UCSF.

Special guests are William H. Danforth, president Washington University; and Robert J. Glaser, President, Henry J. Kaiser Family Foundation.

Some administrators from each university will also attend.

STANFORD—

Site clearance is to begin Monday (Feb. 22) on the $14 million cardiovascular research building, expected to be completed in October 1983.

The 52,000 square foot building will house the academic and research programs of the department of cardiovascular surgery headed by Norman Shumway, Frances and Charles Field professor of cardiovascular surgery; and the division of cardiology, headed by Donald Harrison, William G. Irwin professor of medicine.

Roger Buckhout, project manager, said actual groundbreaking is expected to start March 1, and a formal ceremony marking the start of construction will be held April 14 "at a time convenient to the principal donors to the project."

A $4 million grant in 1979 from the Max C. Fleischmann Foundation of Nevada enabled the university to begin planning for the building. Since then, virtually all of the total has been raised or pledged.

The facility will be located on the east side of the hospital, between the medical center and Stanford Shopping Center.

Currently, the research and office facilities of two premier scientific and patient treatment programs at Stanford have been carried out in crowded quarters scattered throughout the hospital, campus and rented office space on Welch Road in Palo Alto.

On Thursday, Lawrence Crowley, the university's vice president for medical affairs said:

"The research and clinical efforts of the teams headed by Drs. Harrison and Shumway have been carried out despite the handicaps of space. The physical facility will help integrate ongoing research in the two important areas and will permit a more comprehensive attack on outstanding problems of cardiovascular disease,"

The two lower floors of the building will provide laboratory space, while the top floor will house offices. Patient care will continue to be provided at Stanford University Hospital or the medical center clinics.

The project was designed by Hellmuth, Obata and Kassabaum Inc. of San Francisco. Dillingham Corp. of San Jose is the general contractor.

A recent parking lot restriping project has compensated for a loss of parking spaces displaced by the impending site clearing and construction.

STANFORD—

Dr. Marian E. Koshland, an internationally known immunologist, will deliver the ninth annual **Katharine D. McCormick Distinguished Lecture** Tuesday, Feb. 23.

Her talk, "Control of Gene Expression in the B Cell," will begin 5 p.m. in Fairchild Auditorium at **the Medical School.**

Presently a professor in the Department of Microbiology and Immunology at U.C. Berkeley, **Koshland is known** for her basic research in biochemical immunology—especially for her investigations of the structure and function of immunoglobulin chains, as well as the regulation of lymphocyte differentiation, activation, and antibody secretion.

She has served on a number of national advisory boards and editorial boards, is a member of the **National Academy of Sciences,** and is currently president of the American Association of Immunologists.

Koshland received her Ph.D. in immunology from the University of Chicago in 1949, and went on to continue her research at Oakridge, Harvard, and Brookhaven before joining the faculty at Berkeley in 1965.

The McCormick Lectureship honors Katharine Dexter McCormick, who donated $5 million to **Stanford Medical School** in 1969 with the expressed wish that it be used "for the encouragement and assistance of women pursuing the study of medicine, in teaching medicine and in engaging in medical research."

Katharine McCormick was a co-founder of the League of Women Voters and a vigorous champion of women's rights.

Previous McCormick speakers at Stanford include Drs. Maria I. New, Rose O. Payne, Rita Levi-Montalcini, Elizabeth D. Hay, Barbara M. Korsch, Rosalyn Yalow, Helen M. Ranney, and Mary Ellen Avery.

Koshland's lecture will be open to the public, with continuing medical education credit available to M.D.s. A reception in the Fairchild lobby will follow the presentation.

DNA DEMYSTIFIED IN INFORMATIVE AND FUNNY FILM FOR PEOPLE WHO HATE SCIENCE

STANFORD—

DNA: it's splashed across the covers of national magazines, heralded as the source of new medical miracles, and discussed in universities and "think tanks" across the country. But do you know what DNA really is?

If not, there's a new film by a Stanford University medical student that will gently coach you through the ABC's of DNA.

Medical student Joe Sachs, who is also working on his masters degree in film, produced the 15-minute educational comedy in order to demystify that grand chemical of genetics, DNA (deoxyribonucleic acid). He will introduce the feature at its premiere performance Sunday, February 28 at 2 p.m. at the New Varsity Theater in Palo Alto.

For Sachs, one challenge in producing the film, called "Just What is DNA?," was to explain a complex aspect of biochemistry to people who know nothing about it. "I have always been interested in health education," he explains, "but I wanted to approach the field in a creative way."

The result Sachs himself describes as a "fast-moving 'Sesame Street' for adults."

The film opens in a classroom where diligent students scribble notes furiously in an effort to keep up with a professor who is speaking way over their heads about the chemical structure of DNA. The panning camera stops when it reaches the "hero" of the film, a perplexed student named Arnold, who scratches his head and, in frustration, asks the camera "what the hell is this guy talking about?"

The heart of the film is Arnold's whimsical odyssey in pursuit of knowledge about the genetic material. He is guided in his quest by an all-knowing, invisible narrator who leads Arnold, along with the audience, through a maze of information presented in a combination of striking visual metaphors and colorful animated sequences.

By the end of the film, Arnold feels self confident enough to discuss DNA with Stanford biochemistry professor and Nobel laureate Paul Berg—in fact, he has learned so much that, at the close of the film when Berg recapitulates some basic information about DNA, Arnold, the former nucleic acid novice, slyly tells the audience, "I already knew all that."

-more-

The film represents Sachs' first endeavor in the cinematic world. He entered Stanford's master degree film program without any previous knowledge of the craft, but with considerable enthusiasm. "Entering film school had always been a fantasy of mine," he recalls.

If the film had been commercially produced, Sachs estimates it would have cost about $50,000, the animation alone about $10,000. But the student film crew and actors (Jay Martel played Arnold) donated their time, and Sachs and an undergraduate collaborator taught themselves animation. Sachs himself financed the remainder of the production costs, about ten percent of the overall estimate.

The film has been in the works for about a year, beginning with the script-writing phase last spring. Sachs put aside his medical studies briefly to work fulltime on filming and editing the project, continuing with the sound and animation portions during summer and fall.

Now Sachs hopes to find a distributor for the film, which is generally aimed at high school and junior college audiences, as well as for adult education. He also confesses a desire to explore the possibility of showing the film to a national audience, perhaps through an educational television network such as the Public Broadcasting System.

But regardless of its eventual fate, the DNA film has served mainly as a demonstration project, says Sachs, to show himself (and others) how basic science knowledge could be approached entertainingly and informatively through the medium of film.

His next project will be more clinically inclined, says Sachs, and during his upcoming clerkships he plans to be looking at what areas of medicine need demystifying.

Farther into the future, Sachs sees himself spending half of his time in clinical medicine and half-time working on health education projects.

Faculty consultants who assisted Sachs in the DNA film were Lubert Stryer and Roger Kornberg, professors of structural biology; Paul Berg, professor of biochemistry; adjunct communication professor emeritus Julian Blaustein and adjunct communication professor Ron Alexander.

STANFORD—

Dr. Kenneth P. Johnson, a neurologist from the University of Maryland School of Medicine, will deliver the sixth annual George A. Zimmermann Lecture at Stanford University Medical School on Feb. 18.

His talk, to begin at 5 p.m. in room M106, will be on the "Current Status of Experimental Therapy of Multiple Sclerosis." It is open to the public.

Johnson, an internationally recognized authority on demyelinating diseases (multiple sclerosis and related disorders), is professor and chairman of the Department of Neurology at Maryland. He has made a number of important contributions in the fields of neuroimmunology and neurovirology, and has been instrumental in the development of cerebrospinal fluid examination in the diagnosis of demyelinating diseases.

A graduate of the Jefferson Medical College and former professor of neurology and pathology at U.C. San Francisco, Johnson is the author of more than 80 papers in the medical journals and books.

The Zimmermann Lectureship was established by the Department of Neurology in 1977, as part of a gift by the late George A. Zimmermann, a long-time San Francisco businessman.

STANFORD—

"The Child: Optimizing Growth and Development" will be the focus of this winter's Progress in Medicine lecture series, a community outreach program sponsored by the Stanford University Medical Center.

The quarter will open Feb. 24 with an introductory presentation by Dr. Irving Schulman, professor and chairman of the Department of Pediatrics.

Also speaking will be Dr. Philip Sunshine, professor of pediatrics and director of the intensive care nursery. He will discuss "New Concepts of Nutrition in Infancy," with an emphasis on the immunological and environmental aspects to the use of human milk.

On March 3, Dr. Bryna Siegel-Gorelick, a postdoctoral fellow in the Division of Child Psychiatry and Child Development (Department of Psychiatry), will speak about "Early Day Care and Implications for Child Development." Her discussion will include types of day care, a review of the research, and the application of child development knowledge in choosing and using day care.

Dr. Ron G. Rosenfeld, assistant professor of pediatrics, will lecture on "Growth in Childhood," and new approaches to the evaluation and management of growth disorders, March 10.

The Progress in Medicine lectures were initiated at Stanford in 1966 by Dr. Joshua Lederberg, then professor and chairman of the Department of Genetics, to provide an opportunity for leaders in academic medicine to share their insights and perspectives with the community.

Lederberg had observed: "The community has little opportunity to be informed of the exciting developments in medicine. Public understanding of these developments is of the utmost importance to social decisions."

This year the series focuses on a single theme—the development of the child. "The Science of Birth" was part one, taking place during the fall. The spring schedule will be announced at a later date.

All winter quarter presentations will take place in the Medical Center's Sherman Fairchild Auditorium, at 7:30 p.m. Admission is free, and seating is limited. There are no reserved seats, and no tickets will be issued. Early arrival is recommended to permit the best choice of parking and seats.

For further information and registration forms, call the Medical Center's Office of Public Events, at 497-6389.

SLEEP—WAKE COMPLAINTS DIAGNOSED IN FIRST LARGESCALE STUDY

STANFORD—

A nationwide study of nearly 5,000 patients suffering from insomnia and other sleep disorders may help clinicians pinpoint the most appropriate treatment for each case.

"This was the first time that a large number of patients with sleep-wake complaints have been diagnosed by both a common classification system and objective sleep monitoring." said Dr. Richard Coleman, co-director of the Stanford Sleep Disorders Clinic,

"Identifying and diagnosing sleep-wake complaints increases the potential to treat them properly," said Coleman, a clinical psychologist who headed the study.

Since a variety of causes may be responsible for conditions exhibiting similar symptoms, "clinicians may need to pay closer attention to precise diagnoses since treatment can differ depending on the exact condition," said Coleman.

The investigation included Stanford and 10 other specialized sleep disorder clinics across the United States which are members of the Association of Sleep Disorders Centers.

The results, compiled by Coleman and 16 co-authors, were published Feb. 19 in the **Journal of the American Medical Association**.

The four major diagnostic categories were insomnia, excessive daytime sleepiness, sleep-wake schedule disorders and parasomnias (abnormal behavior during sleep such as sleepwalking).

Insomnia accounted for about one third of all patients studied, and 35 percent of this sleepless group were found to be suffering from psychiatric disorders such as depression or chronic anxiety.

"Although short-term sleeping medications together with psychiatric referral might be appropriate treatment for these patients, the same medications are dangerous in another smaller group of insomnia patients, the 6.2 percent suffering from sleep apnea syndrome.

"Such individuals awaken during sleep because of a halt in breathing, so sleeping pills might interfere with the body's ability to arouse itself when breathing stops."

Other important causes for chronic insomnia included stress disorders, periodic leg movements causing awakenings during sleep, and drug or alcohol dependency.

-more-

"A wide variety of conditions can be responsible for insomnia. Persistent stress-insomnia patients, for example, may benefit from a combined program of sleep hygiene, relaxation and counseling."

In another group of patients, doctors found no objective signs of insomnia on the nocturnal sleep test, which involves all-night monitoring of brain waves, eye movements, cardiorespiratory functions and muscle activity.

"These individuals simply underestimate their total sleep time, and for them, reassurance rather than medication is indicated."

Sleep apnea, 43 percent, and narcolepsy, 25 percent, were the largest categories among pateints who were abnormally sleepy during the day.

"If significant daytime sleepiness exists, then sleep apnea and narcolepsy become the primary diagnostic possibilities. Until the past few years, these conditions were frequently confused for one another. The symptoms are similar but the treatment is not.

"Stimulant medication may help narcoleptics but could be dangerous for sleep apnea patients who may instead need surgery."

Persons who fell asleep inappropriately during the day outnumbered insomniacs 1,983 to 1,214, but Coleman believes that this doesn't necessarily mean excessive daytime sleep (hypersomnia) is more prevalent than insomnia.

"People who fall asleep in embarrassing or dangerous daytime situations, for example while driving or at work, are more motivated to seek help at a sleep center."

Another malady, disorders of the sleep-wake schedule, probably were underrepresented in the study, because these syndromes only recently have been described. These conditions are marked by unconventional and abnormal sleep schedules, and include, for example, persons who regularly cannot fall asleep until 4 or 5 a.m., even though they try to live on a normal daytime schedule.

"Often people with sleep scheduling disorders do not think of their condition as a medical problem and hence do not seek help from a sleep clinic. Therefore we do not have a really good idea of their prevalence at this point," Coleman said.

About 15 percent of the studied patients suffered from a wide range of parasomnias, such as sleepwalking or nocturnal seizures.

The researchers emphasized that the patients included in the study represented referrals of longterm sufferers of sleep-wake disorders to sleep clinics. Many people, Coleman said, experience temporary insomnia or even daytime sleepiness, often as a result of a crisis.

"These individuals generally do not require referral to a specialty sleep clinic. Often consultation with a family physician, short-term medications, or the passage of time alone are sufficient," Coleman said.

A total of 4,694 patients were studied, including 798 persons evaluated with sleep monitoring for impotency.

ASIAN EDUCATOR SEES GIFT MATERIALIZE

STANFORD—

A dedication ceremony was held last week at the Medical Center to open the new Wilson T.S. Wang Library in the Division of Otolaryngology/Head and Neck Surgery, and to honor the Hong Kong resident for whom it was named.

A former patient in the Division, Mr. Wang donated a total of $108,000 towards development of the library, now ready for use in room R117 of the Medical Center.

"He walked into my office with a checkbook and asked, 'What does your program need that I might help with?' " recalled Dr. Willard E. Fee, Jr., chief of the Division and Wang's primary physician while he was hospitalized almost two years ago.

Wang, speaking at the ceremony, said he knew from experience on a hospital board in Hong Kong—and by the budgetary constraints faced in this country—that no physician would turn down his offer.

"And I wanted to somehow pay for a part of my care which didn't appear on the bill—the wonderful, personal concern of every doctor, nurse and staff person I came across.

"It seemed a blessing in disguise that I had come here for medical treatment, because I left with the feeling that I'd made many new friends," he said.

Guest speaker at the ceremony Dr. Lawrence G. Crowley, vice president for medical affairs, noted, "This is the first time we've been privileged to honor a citizen of an Asian country in this way at Stanford Medical Center."

He pointed out that the plaque awarded Wang, printed in both English and Chinese, is a symbol of the Medical Center's aim to be a medical resource for patients on both sides of the Pacific.

Agreed Wang, "The number of miles between us doesn't make a difference. The world is big or small, just depending on how you look at it."

Another special guest at the ceremony was Mrs. I. James Quillen, widow of the former dean of Stanford's School of Education, which Wang visited 32 years ago under a State Department program.

Wang is the owner and director of Hong Kong's New Method College, consisting of five private elementary and high schools in the city. New Method is the largest college of its kind in Hong Kong.

According to Fee, developing the new library has involved much renovation and reconstruction since the project began last April. "Before, we had only a small library. Now it's a nice-sized facility."

An especially proud feature of the new library is a self-contained, sophisticated projection system with capacity for many kinds of audio-visual activities. The system, which includes such equipment as a double screen, a tape recorder, a selection of video tapes, and more, was custom-made for the Division as a part of Wang's gift.

STANFORD—

Nancy Lassen, who Jan. 20 became Stanford's sixth heart-lung transplant patient, died Friday (Feb. 12) after doctors determined she had slipped into an irreversible coma.

Physicians disconnected the respirator which had supported her heart and lung functions in midmorning, some 20 hours after the second of two electroencephalogram (EEG) tests determined the 26-year-old native of Grand Island, Neb., had been brain dead for at least three days. Time of death was listed officially as 11:05 a.m.

"We will be performing an autopsy to determine what caused Nancy Lassen to slip into a coma," said Dr. Bruce Reitz, her physician.

Complete autopsy results are not expected for at least six weeks, because the brain tissue which might offer the key to the unexpected death must be chemically treated for that long, Reitz explained.

Reitz, an assistant professor of cardiovascular surgery who has performed all six of Stanford's six heart-lung transplants, said Lassen had slipped into a coma Feb. 4.

Lassen's condition was critical but stable shortly after surgery, even though she suffered from kidney and liver damage and exhaustion after a five-year battle against pulmonary hypertension, a usually fatal lung disease of unknown origin which subsequently damages the heart.

"It was clear that at the time of surgery, she only had a few weeks to live and that the transplant operation offered her only hope for survival," Reitz said.

Like several of her predecessors, she was placed on kidney dialysis a few days after surgery, but unlike the others, her kidney function did not return.

"We simply do not know at this time whether any or all of these conditions contributed to her slipping into the coma which ultimately led to death, and this is what we hope the autopsy to determine," Reitz said.

-more-

Reitz said the program is continuing and two persons currently are waiting for the operation.

Lassen's family, including father, mother, stepmother and four sisters joined in the decision to withdraw the artifical life support system, Reitz said.

Lassen, who lived the past year in Phoenix with a sister, was single and had worked as a professional nurse until she was forced to quit because of ill health last October, nearly five years after she developed pulmonary hypertension while attending nursing school in Nebraska.

Surviving are her father and stepmother, Robert and Shirley Lassen of Grand Island, Neb., and her mother, Lilla Lassen, also of Grand Island.

The sisters include Jan Mohs, 30, Menlo Park, Calif.; Barbara Huff, 28, Phoenix; Sally Lassen, 22, and Jeanie Lassen, 20, both of Lincoln, Neb.

The family said a memorial service is scheduled at the First Presbyterian Church, Grand Island, Neb. 68801, at 2 p.m., Feb. 20. In lieu of flowers, the family requests contributions to a Nancy Lassen Memorial Fund, which will be used for a nursing scholarship. The church is coordinating the fund, the family said.

Heart-lung transplants began at Stanford March 9, 1981, after more than 10 years experience with more than 200 heart-only transplants. Cyclosporin A, a fungal derivative, made feasible the dual organ transplants.

Four of the first six heart-lung transplant patients are living and have returned to productive activity.

STANFORD—

Stanford University Hospital is not prepared at this time to sign a contract to participate in the Pentagon's controversial Civilian-Military Contingency Hospital System (CMCHS), the Hospital's board of directors decided Wednesday.

Instead, the board said the Hospital will "continue to participate in all appropriate regional and other disaster preparedness activities and in any appropriate network.

"The Hospital is also committed to assisting in the rapid response to civilian and military casualties by attempting to provide whatever beds it can without violating its commitment to its local and broader communities."

The CMCHS contains provisions that the Hospital is unprepared to accept, the board said. Among them are provisions calling for commitment of a specific number of beds for use by war casualties and the release of certain personnel information, including employees, military affiliations, either past or present.

But instead of rejecting a contract outright, as some hospitals have done, the Board left open the possibility of further exploring these issues with the Department of Defense. The Board directed Hospital officials to consult with other teaching hospitals and to initiate discussions.

The Board said certain provisions in the CMCHS proposal did not appear to be essential to the Hospital's commitment to the national effort, in addition to resulting in unnecessary expenditures.

The goal of the CMCHS is to make 50,000 civilian hospital beds available to receive injured soldiers airlifted from battle zones, such as Western Europe. Analysts have noted that civilian hospital participation would be vital to provide care for U.S. casualties following a limited war.

Opponents, including a national anti-war group, called Physicians for Social Responsibility, have said that planning for the results of a nuclear exchange creates the unrealistic expectation that a viable response is possible.

In December, the Hospital's medical board had recommended to the Hospital Board that no contract be signed with the Department of Defense.

The medical board, which represents the medical staff of community and faculty physicians, had suggested that the hospital should inform the government on a continuing basis about the number of beds which might be available for wartime emergency patients, but objected to reporting personnel information.

TRUSTEES APPROVE MEDICAL SCHOOL TUITION INCREASE OF 15.0 PERCENT.

STANFORD—

A 1982-83 tuition increase of 15.0 percent for M.D. students in Stanford's School of Medicine was approved today (Tuesday, February 9) by the University's Board of Trustees.

The Trustees' action brings the 1982-83 tuition rate per regular quarter to $3,197 for medical students, a rise of $417 over last year's quarterly tuition of $2,780; the nine-month tuition at the Medical School will be $9,591, an increase of $1,251 over last year's $8,340 tuition fee.

Since Stanford usually announces its tuition fees in advance of other private universities, exact rates of increase for other medical schools are not as yet available.

However, preliminary figures recently circulated among the financial officers of several major private medical schools place Stanford's tuition hike somewhere in the mid-range, according to Medical School controller Kathleen Roberts.

Dr. John Steward, associate dean for student affairs, noted that about 80 percent of Stanford M.D. students receive loans or other sources of financial aid to support their medical education. As in past years, the Medical School intends to provide aid to all students who demonstrate financial need through the coming year, Steward said. However, federal cutbacks in financial aid programs and higher interest rates could cloud the Medical School's future ability to meet the demonstrated need of every M.D. student, Steward added.

Under the current medical school tuition program, M.D. students are charged for 13 quarters of study, regardless of the number of quarters for which they register. They pay a special fee for quarters beyond the thirteenth—the terminal graduate registration fee—which for 1981-82 was $200.

This policy, adopted in 1980, encourages medical students to spend more than four years in medical school so that they may participate more fully in the Stanford program and elective scholarly acitivities, according to Steward.

Last year, medical school tuition at Stanford was boosted by 13.6 percent.

(This year's Medical School tuition hike was granted by the Trustees along with a 15.1 percent increase in tuition for Stanford undergraduates, a 15.5 percent increase in room and board rates for undergraduates and a 14.8 percent increase for students in the Law School.)

STUDY TO ADD PUNCH TO MEDICINE'S MANAGEMENT

STANFORD—

A major project to develop, test, and implement new management techniques for the practice of medicine in the academic setting has been launched by the Stanford University School of Medicine.

The project, initiated by a $50,000 grant from the Commonwealth Fund of New York will be centered in the Department of Medicine, the largest clinical department at Stanford employing about 20 percent of the Medical School's faculty.

A two-step process will be involved in the study, according to David S. P. Hopkins, director of analysis and planning at the Stanford University Medical Center. The first step will be a 10-year retrospective analysis of changes in the Stanford Department of Medicine and four other departments of medicine at selected academic health centers.

The second step, for which additional funding will be sought, will entail the development of a computer-based strategic planning system.

"Such a system," Hopkins explained, "would enable departmental chairmen to do better projections of revenue changes, plan for new academic programs, and determine compensation plans for their faculties."

Hopkins specializes in development of computer-based planning models for university administration and financing. He is co-author (with William F. Massy) of a recent book on this subject by the Stanford University Press. He will co-direct the project with Dr. Kenneth Melmon, chairman of the Department of Medicine at Stanford. Participating department of medicine chairmen from other schools are: Dr. Philip Fialkow (University of Washington, Seattle), Dr. Richard V. Hornick (University of Rochester), Dr. Arthur Rubenstein (University of Chicago), and Dr. Kennith Shine (University of California at Los Angeles).

-more-

According to Dr. Melmon, the growth of faculty in schools of medicine has been staggering in recent years. This growth is substantiated by figures showing that the number of salaried faculty clinicians in the United States increased from 2,200 in 1950 to 36,500 in 1979.

"Many departments of medicine now have revenues in excess of $30 million a year," Melmon said, "and there's general agreement that chairmen are administratively overwhelmed."

Moreover, since most chairmen are clinical scientists who for career reasons take up administrative duties on a short-term basis, there is continuing turnover of chairmen whose tenure on the job is less than six years. It has been estimated that at any given time as much as 20 percent of Medicine chairmanships are undergoing change.

Improved information and planning systems will most probably not eliminate this problem, Melmon said. But it would give chairmen quick access to accurate information relating to the management of their departments and compensation of their faculty.

Traditionally, he explained, medical education has been supported by tuition, grants, private gifts and patient care revenues. Until recently the association between sources of funds and their actual programatic use has been somewhat informal.

For example, revenues generated by patient care have been available for funding a portion of teaching and research, he said. The tightening of public expenditures for medical care and research and demands for stricter accountability have led to greater dependence on each source to cover just the main purpose for which it was intended.

Moreover, he said, medical school departments must cope with new technologies, and shifts in the mix of skills needed to treat patients as patterns of illness change.

"This is why improving the administrative capabilities of departments in schools of medicine is especially important now," Melmon said.

Toxic shock syndrome discussed

STANFORD—

Toxic shock syndrome (TSS) is a dramatic illness affecting nearly every organ system of the body. It can often lead to shock and even death if not properly treated.

Though commonly associated with tampon use, 10 percent of TSS cases do not even occur in conjunction with menstruation, said Dr. Iris Litt at a recent Pediatrics meeting.

Furthermore, at least one autopsy of a TSS victim showed that the woman had not been using tampons at all.

"Wound infections and abscesses are the usual sites for the TSS bacterium, called *Staphylococcus aureus,* in these cases," explained the associate professor of pediatrics and director of the Division of Adolescent Medicine.

And though almost all the literature so far on TSS has appeared in fields other than pediatrics, she said, 11 to 19 year-olds account for 42 percent of the disease's incidence.

"The majority of TSS cases involve tampon users below the age of 19, though the reasons for this are still a mystery," she said. "This group composes only 17 percent of the total number of tampon-using women in this country."

Litt, who serves on the Institute of Medicine's committee on TSS, went on to describe other mysteries surrounding the disease. "Though it's a rare one, there are currently 45 to 60 cases reported nationwide each month," she said. "But outside the U.S., there have only been 150 cases reported worldwide, ever—and only in 12 countries." (Later questioned about the possibility of tampons elsewhere being made of different materials, Litt dismissed this as untrue.)

She continued, "There are lots of remaining questions regarding the epidemiology of TSS. For example, in menstruating women, 98 percent of patients are white. But in non-menstrual cases, the races are represented in proportion to their numbers in the total population."

TSS patients manifest a predictable range of clinical symptoms. Within the first four days of menstrual cases there are changes in skin and mucous membranes. Also apparent early on are high fever, headache and vomiting, diarrhea, confusion, abdominal pain, and weakness.

The phenomenon known as "strawberry tongue" is common, as is a history of diarrhea. Later, patients develop mouth ulcers, rashes and other dermatologic problems, with a loss of hair and nails reported between 60 and 90 days of onset.

While a variety of abnormal lab tests, some fairly consistent, are observed, said Litt, none are yet diagnostic. TSS symptoms seem to resemble those of various other diseases—a fact which often led to misdiagnosis in the past.

"Treatment has been hampered by lack of any controlled studies," she said. "Specific therapy includes the use of beta-lactamase-resistant antibiotics, though evidence so far shows only that these reduce the likelihood of recurrence in first-time patients." 35 percent of all TSS patients experience recurrence within three months, she explained.

-more-

"Those who are treated with these antibiotics *and* stop using tampons have a recurrence rate of only 15 percent. By contrast, those who are not treated and continue using tampons have a 75 percent recurrence rate."

Other treatments currently being tried include hemodialysis and steroids but, said Litt, "A complete investigation remains to be done."

For one thing, the connection with tampon use, though obvious, is still not fully understood. "Since Proctor and Gamble withdrew Rely tampons from the market after the press first reported a possible association with TSS in the summer of 1980," said Litt, "the incidence of the disease has not significantly decreased, much less disappeared.

"Except during the peak period of mild hysteria when the number of cases reported shot up, TSS has not let up—especially not in non-menstrual cases."

At the time the connection with tampon use was first noticed, she said, Rely happened to be the brand used by most TSS patients. But since then, "the other popular brands have taken up the slack."

The degree of absorbancy, she said, appears to be a determining risk factor. The greater the absorbancy, the higher the risk. Only in recent years have synthetics and other materials been added to the cotton in tampons to increase absorbancy.

Also, the bacterial organism found in the genital region of women with TSS (though discovered as well in some other women) has appeared to be toxin-producing only in the past decade.

Whether these observations are coincidental or not remains to be seen.

Certain variables thought to be TSS risk-producing but proved otherwise by research include personal hygiene and sexual activity, said Litt. "Some studies, however, do indicate a difference in risk between continuous and discontinuous use of tampons."

Litt said doctors should advise their patients not to use tampons at all. "But realistically, we can't expect all women to follow this counsel." (A year after the media focused attention on TSS, she recalled, 60 percent of the women who at first had stopped using tampons returned to them.)

"Patients should be told if they must use tampons to make sure they're not using the high or super-absorbancy kinds," said Litt, "to change them every four to six hours, to use pads at night, to wash their hands before tampon insertion, and to use an applicator for insertion."

Preliminary studies indicate, she said, that too much handling of tampons may contribute to risk factors in TSS.

"If a woman notices symptoms, she should remove her tampon immediately and save it for culturing. And she should seek medical help."

The fatality rate associated with TSS, usually between three and 14 percent, seems to be dropping off recently with improved treatment, said Litt.

"But," she added, "the challenge to modern medicine of becoming more effective in preventing this disease is still before us."

TWO STORIES: WEXLER IS FELLOW; PROGRAM GIVES WORKSHOPS: Lisa Ames (415) 497-6911

STANFORD—

Dr. Lewis Wexler, professor of radiology, has been named one of six Robert Wood Johnson Health Policy Fellows for the academic year 1982—83.

Run by the Institute of Medicine, a branch of the National Academy of Sciences, the program was started in 1974 with a grant from the Robert Wood Johnson Foundation of Princeton, New Jersey.

Fellows are chosen on a competitive basis from nominations by academic health centers across the country. All mid-career health professionals, they spend a year in the nation's Congressional offices, studying and participating in the processes by which health programs and policies are formulated.

The dissemination of this new knowledge upon their return is hoped ultimately to improve understanding between the government and medical faculties.

A faculty member at Stanford Medical School since 1967, Wexler for the past two years has served on the board of the Santa Clara County Health Systems Agency.

"I wanted to expand my horizons," he says, explaining that one of his main interests is the impact of governmental policy on the functioning of academic medical centers.

Wexler plans to begin his year in Washington, D.C., when the program starts in September.

STANFORD—

The Community Outreach Project of the Primary Care Associate Program is offering a series of informative workshops this month to introduce the program to interested members of the community.

Especially intended for those thinking about applying to it, the workshops will acquaint participants with the program's facilities and opportunities, and help to answer their questions.

Prospective students in the program—which trains physicians' assistants and family nurse practitioners—will be able to review their applications, prepare for interviews, and discuss in depth any particular phase of the program in which they have a special interest.

To be held in room A106 of the Medical Center, the workshops will take between two and three hours. The remaining sessions are: Feb. 11, 7 p.m.; Feb. 13, 10 a.m.; Feb. 23, 7 p.m.; Feb. 25, 7 p.m.; and Feb. 27, 10 a.m.

Reservations are required, since space in each workshop is limited. Those interested should call 497-6431 to schedule in advance.

The Primary Care Associate Program is currently accepting applications for the semester beginning Sept., 1982. All interested individuals should call the above number for further information regarding prerequisites and courses offered.

BRAIN STIMULATION AID FOR CEREBRAL PALSY TO BE TESTED

STANFORD—

A technique of electrical stimulation of the brain as a treatment for improving function in patients with cerebral palsy will be evaluated in the coming 18 months by Stanford University researchers.

The project is designed to assess the claimed clinical benefits of the treatment, and to hopefully end a medical controversy surrounding the procedure, according to Dr. Richard H. Britt, assistant professor of surgery and director.

"If the results of the Stanford study turn out to be as positive as earlier claims, the technique might be rapidly accepted, leading to significant improvements in the lives of some 700,000 disabled patients in the United States," Dr. Britt said.

The study, funded by a $149,970 grant from the Robert Wood Johnson Foundation of New Jersey, is one of 23 new projects aimed at helping people impaired by disease, disorder or injury to regain their ability to perform the tasks of everyday living, the Foundation has announced.

The technique, known by the technical name of "cerebellar stimulation," was introduced in the early 1970s by Dr. Irving Cooper, a New York neurosurgeon. It combines the use of an implantable pacemaker that provides continuous electrical signals to stimulate the cerebellum like a pacemaker regulates heartbeat. The cerebellum is the lower back part of the brain that controls body-balance and muscular coordination.

"About 1,000 patients with cerebral palsy have been implanted with first generation of cerebellar stimulators over the past decade," explained Dr. Britt.

"Prospective studies have indicated that between 60 and 90 percent of patients with cerebral palsy benefit from the procedure."

Evidence for this comes from Dr. Cooper's own studies of the technique which showed improvement in speech communication, and a reduction in spasticity allowing patients to function in terms of being able to feed themselves, dress and generally take part in activities of daily living, Dr. Britt said.

Dr. Cooper's studies also noted significant improvement of athetoid movements, a condition characterized by constant, uncontrollable slow motion of the fingers, toes, hands, feet and other parts of the body, he said.

-more-

More recent research by Dr. Ross Davis of Mount Sinai Hospital in Miami, Fla., seems to corroborate these findings.

"In his experience," Dr. Britt said, "the primary effect of cerebellar stimulation has been a lowering of spastic muscle tone in 90 percent of his patients."

But in contrast to these glowing reports, Dr. Britt explained, controversy has arisen as to the "real" benefit of cerebellar stimulation.

The criticisms derive from results of studies involving only limited numbers of patients, he said. These studies have indicated that if the observers and patients do not know whether the stimulator is on or off, no differences can be detected between control and stimulated patients.

The patients in some studies had stimulators of different types with different electrode arrays and a wide range of stimulation rates. In some instances the stimulators did not work, distorting the research conclusions.

"For this reason," said Dr. Britt, "clinicians dealing with cerebral palsy children and adults agree that a well-designed double-blind, cross-over study is required to prove the value of cerebellar stimulation."

In the Stanford project, which has received approval from the human subjects committee, 50 patients with significant spasticity will have placement of a totally implantable stimulator developed by Pacesetter Systems, Inc. of Sylmar, Cal., a leading manufacturer of cardiac pacemakers, Dr. Britt explained.

The stimulator, called the Neurolith system, operates on a lithium-iodide battery replaceable every five years. The electronics of the device and battery are encased in an ultra-thin 3 x 2-inch metal box similar to those used for heart pacemakers. The device is implanted by a simple surgical procedure at the abdomen under the skin where it protrudes as a slight bump. Tiny electrodes tunneled through the skin connect the device to the back of the brain through two tiny openings.

Several specialists will participate in the study. They include Dr. Dorothy A. Huntington, an associate professor and specialist in speech and hearing science; Dr. Barry R. Tharp, an associate professor of neurology; Dr. Eugene E. Bleck, professor of clinical surgery specializing in the orthopedic management of children with cerebral palsy; Thomas Ryan, research associate; and Claire Houston, R.N.

STANFORD—

Dr. Roger Kornberg, professor of structural biology at Stanford University School of Medicine, has been selected to receive the 1982 Passano Foundation Young Scientist Award.

Kornberg, who is 34, is being honored for his research on the structure of chromatin, the protein/nucleic acid complex that encodes hereditary information in the cells of higher organisms.

On March 30, 1982, he will receive the award and a $5,000 honorarium at the Passano Foundation's award-presentation dinner in Baltimore.

Kornberg's work on chromatin structure is helping to explain how the orderly expression of genetic information is accomplished in cells.

In 1974, he proposed a three-dimensional model of chromatin structure which has been widely accepted. The elementary subunit of chromosome structure that Kornberg discovered has been called the nucleosome.

Each nucleosome is a highly ordered collection of eight proteins, called histones, around which a brief stretch of the lengthy DNA double-helix is coiled. Through the electron microscope, nucleosomes look like beads on the string-like chromatin fibers.

The nucleosome's property of holding DNA in a tightly condensed form is thought to help explain how such enormous lengths of DNA can be wound up and packed into the small volume of a cell's nucleus.

The nucleosome structure may also be at the basis of controlled coiling and uncoiling of DNA. Localized unfolding of DNA exposes genes along a short stretch to the cell machinery that eventually enables those genes to be expressed; the re-folding process hides those genes away from the rest of the cell, extinguishing their expression.

Kornberg obtained his bachelor's degree with honors from Harvard in 1967 and his Ph.D. from Stanford in chemistry in 1971. Before coming to Stanford in 1978, he taught biochemistry at Harvard.

The Passano Foundation of Baltimore presents an award each year to one or more individuals who have made an outstanding contribution to medical science in the United States.

Founded by the late Edward Boteier Passano, then chairman of the board of the medical and scientific publishing interest, The William and Wilkins Co., the Foundation has honored more than 40 scientists. Nine have subsequently won a Nobel Prize for their work.

Daniel E. Koshland, Jr., professor in the Department of Biochemistry at U.C. Berkeley, will present the ninth annual Linus Pauling Lecture, Feb. 10, at Stanford University Medical Center.

Koshland will discuss "Sensing and Adaptation in Biological Systems," 4 p.m. in the Sherman Fairchild Auditorium.

The lecture, which is open to the public free of charge, is sponsored by the Departments of Biochemistry, Biology, Chemistry, Genetics, Medical Microbiology, Structural Biology, and the Stanford Magnetic Resonance Laboratory.

Previous speakers have included Nobel Laureates Linus Pauling, Arthur Kornberg, Gerald Edelman, and William Lipscomb; and Drs. Seymour Benzer, Charles Yanofsky, Hugh Huxley, and Harden McConnell.

MEDIA BRIEFING FOCUSES ON SCLERODERMA DISEASE

STANFORD—

Scleroderma, a little known but crippling and sometimes fatal rheumatic disease affecting about 100,000 Americans, will be the subject of a news media briefing at 10 a.m., Wednesday, Feb. 10 in room TA137.

The session is to focus on a dual achievement: For patient Victor Cervantes the session represents a personal triumph over pain and death. For researcher James Fries, an associate professor of medicine at Stanford, the conference punctuates the unraveling of a medical mystery through an experiment involving aggressive treatment.

This is the first media briefing in an informal series Stanford Medical Center expects to sponsor periodically. It is being held in conjunction with National Scleroderma Week, recently designated as Feb. 7-12 by an act of Congress.

Scleroderma, related to arthritis, rheumatism and other diseases of the connective tissues, has been described in medical literature in its most typical form as causing its victims to be "encased like a mummy in a slowly shrinking, ever contracting skin of steel." The origin or cause of the disease is unknown.

The tightening of the skin is caused by scarring of the blood vessels near the surface, and in advanced forms, blood vessel damage may extend into the body and eventually cause malfunction of the lungs and the upper gastrointestinal tract. But in its most ghastly form, scleroderma crisis, the malady causes the blood pressure to rise to catastrophic levels and the kidneys to fail.

This condition, which occurs in about 25 percent of scleroderma patients, was reported as universally fatal within six weeks when Cervantes developed it in 1971. He also suffered from blindness and malignant hypertension (a form of rapidly worsening high blood pressure) as a result of the disease.

Today the San Jose resident's health has returned to near normal, and his personal life has prospered with marriage and a new child.

-more-

And Fries has the satisfaction of helping Cervantes to become the second person in recorded history to survive kidney scleroderma crisis.

The remedy was found in massive treatment with multiple antihypertensive drugs, proving the researchers' suspicion that the disease had a microvascular origin and could be treated by providing relief to vascular injury.

Fries and his colleagues "loaded the patient with toxic doses of five hypersensitive drugs," medication intended to lower Cervantes' blood pressure, the researcher said.

"We just kept on increasing the dosage beyond what ordinary standards would dictate. Of course there were risks. Quite honestly, we ran the risk of increasing the damage to his kidneys. But the man was facing certain death and we had to do something.

"What we found was that when the blood pressure was lowered sufficiently, the damaged blood vessels in the kidney were able to regenerate and permit the organ to regain adequate function."

Today, Fries said, about half of the scleroderma patients who suffer scleroderma crisis are able to survive.

Current research into scleroderma, which as a disease of the connective tissue is related to arthritis, is being funded under a $650,000 bequest from the estate of Hertha Magnus of San Francisco. That money, combined with other funds Stanford currently is soliciting, will fund a two year study on 28 patients to see if the same drugs which saved Cervantes life can be used in smaller amounts to relieve the suffering of scleroderma patients with less lethal symptoms.

Research efforts also include a study of 800 patients suffering from scleroderma and other rheumatoid diseases to determine the longterm outcome of treatment.

Room TA137, site of the news briefing, is in the physical therapy division of the Medical School. It is located in the redwood temporary buildings at the extreme western edge of the medical center complex near the Medical Center News Bureau. Parking is nearby.

Fries and Cervantes will be available to discuss the ailment and their personal reflections on its conquest.

SHERLOCK HOLMES, NEUROSURGERY AND DR. JOHN W. HANBERY

(Editors: Pictures of Hanbery available on request if not included)

STANFORD—

One of Dr. Roy Cohn's favorite stories about his friend John W. Hanbery was born at a cocktail party.

"I was walking by a group of men I didn't know," begins Cohn, a professor of surgery.

"One of these guests was talking about a recent sea cruise and said he kept running into 'a woman who was constantly taking pictures and her husband who stood around smoking a pipe and never said anything.'

"I knew immediately that he was talking about Jake Hanbery and his wife, Shirley."

The artistic, enthusiastic spouse, Hanbery's legendary taciturnity, and even the pipe provide clues to the man who has headed Stanford's division of neurosurgery since 1964.

"He was the one man who could have held this division together for the past 20 years," says Richard Britt, one of Hanbery's 18 former residents and now an assistant professor with a bias for research.

Sucking on a pipe, Hanbery just might look like his favorite non-medical hero, the fictitious Sherlock Holmes. But the resemblance is more striking when you observe the reason that Hanbery has devoted a small part of his largely medical personal library to collecting the works of his hero.

Deduction, cold, clearheaded reasoning, was the ingredient with which Holmes' cases were solved. And Hanbery doesn't disagree that the same sort of deductive reasoning, the same love of problem-solving is the stock in trade of the neurosurgeon.

"Neurosurgery is greatly different from other surgical specialties," Hanbery explains. "For example, you can open and explore an abdomen. You can't open and explore a head."

But a colleague suggests—a bit mischievously—another explanation for Hanbery's love of Holmes: "It just might be because Holmes' trusted confidant was a doctor."

That was not a remark offered totally in jest. It reflects Hanbery's almost singleminded interest in his profession.

"My interests (Holmes, general history and travel nonwithstanding) are clearly related to my profession," he admits.

Even the taciturnity, the lack of interest in small talk and perhaps even some social amenities reflect what many of his colleagues and former students perceive as nearly compulsive dedication.

"His work sort of occupies his entire being," explains Britt.

"He is such a straight shooter that he probably does offend some people," comments another former resident, George H. Koenig, who now practices in Redwood City and Palo Alto.

"If you haven't distinguished yourself in caring for a patient, you'll really hear about it," continues Koenig.

"But his real personal strength reflects in his teaching.

"The thing that first impressed me as a student, was when he explains something to you, it's so clear that if you don't understand it, it's got to be your fault," Koenig adds.

-more-

Britt and another former resident, now associate professor Gerald Silverberg, attest to the seeming conflict between a brusque manner, strong friendships, and excellence in medicine.

"He has more strong friendships over the years than many people who give a more pleasant first impression," says Silverberg. "Of all the people who have influenced me in my life, he is the strongest....He never abandons a patient, he always admits a mistake. But he is more likely to be right than anyone else in neurosurgery."

Another former resident, Don Prolo, now a practicing neurosurgeon in San Jose, says, "I always felt fortunate that we were all working for a man who is smarter than we are."

Hanbery's former students without contradiction believe that their former mentor was a leader, almost a father figure.

(Not all of the former students are "sons," by the way. Frances Conley, now as recently promoted to associate professor of neurosurgery, was the 1969 resident with Hanbery).

"He's fiercely loyal to the people he has accepted into his program," says Britt. "He is bound and determined once he has selected them to ensure they are excellent neurosurgeons," after completing a five-year residency in what might arguably be called the toughest subspecialty in medicine.

"He will guarantee by the sweat of his own brow that you will be a competent neurosurgeon and a credit to Stanford," says Koenig.

Britt explains that "one of the keys to his (Hanbery's) teaching success, beyond his enormous dedication and expertise is that he combines a unique intellect with a lot of common sense."

If anything comes before his students, it's the patients. And perhaps unusual in a teaching hospital setting, Hanbery won't hesitate to place patient care ahead of research when warranted.

Prolo recalls an incident from his residency days:

"I was working on a paper and needed to run a pneumoencephalogram on a patient to round out my results. The test was unneccesary for the patient's health. It would not have been harmful, although it might have been mildly uncomfortable for the patient. But it was vital for my research.

"But Jake said, 'screw your paper.'

"Sure I was angry at the time. But he was right."

Although he engaged in basic research in his early career—and has since aggressively fought for research programs spearheaded by his colleagues—Hanbery remains primarily a clinical doctor and teacher and believes that the emphasis on basic research may have been carried too far in such an exacting specialty in a university setting.

He favors "a more pliable system" which would not penalize the careers of academic physicians who wish to concentrate on clinical activities and research in favor of basic research.

"I think there are certain fields in medicine—and I think neurosurgery is one of them—where one ought to be able to achieve the same degree of acceptance academically whether one takes a clinical route or a laboratory route."

The demands of saving lives using the intricate tools of a specialized surgeon—along with teaching duties—might preclude a dedicated doctor from giving full attention to research duties.

The 18 neurosurgeons who have completed the program have honored their mentors in two formal ways. Late last year, the residents announced at a formal banquet that they had established a John and Shirley Hanbery Scholarship in the Neurological Sciences.

The fund totals about $20,000 and includes contributions from every one of his former residents, along with gifts from other friends.

And earlier, in 1974, the first 10 residents founded the John W. Hanbery Society which meets annually.

-more-

The gathering is hosted each year by a different resident, usually at a resort.

The sessions are enjoyable reunions, say the participants, with Hanbery as guest of honor. But they also involve serious discussions, and all members present a paper.

"It's utterly amazing how some of these guys who probably would never present a paper under any other circumstance will scratch their heads and work throughout the year to prepare a paper which will be acceptable to this very, very tough audience," explains one of the society members.

Physicians who don't know Hanbery very well sometimes find it curious that he spends many hours each week reviewing industrial accident cases. But even this serves the dual goals of education and patient treatment, his close colleagues believe.

"I think he genuinely feels that a university has an obligation to serve the community," explains Britt.

Koenig agrees with this assessment but sees another purpose:

"This sort of work generates a lot of referrals, particularly of lower back problems which are the mainstay of any neurosurgeon in private practice. "And I think Jake Hanbery believes he has an obligation to ensure that his residents have plenty of experience with this sort of work during their training."

Hanbery, of course, was once a student himself. Both he and his wife, the former Shirley Wendt, are virtually pure Stanford products, starting here as undergraduates. In fact, as Prolo likes to tell, the couple met at a preregistration "Jolly-Up Dance" in 1938.

During that first meeting, Hanbery might have told his new friend—who since then joined him in raising four children, now aged 29 to 37—that he intended to be a doctor:

"By high school, there was no doubt in my mind that medicine was what I wished to go into."

But his desire to become a doctor "was deeply colored" while at age 7 he spent about two months in the hospital recuperating from osteomyelitis of the hip, an ailment which has left some physical side effects to this day.

"There was a deep patient/physician relationship which developed between me and my treating physician, Burns Chaffee, who at that time was I think the leading general surgeon in my hometown of Long Beach."

Hanbery may be faintly fearful that his cherished boyhood memory of a doctor who helped him recover at Seaside Hospital in Long Beach might be misinterpreted as a cliche.

"Look," he explains forcefully. "There was never any time when I was 7 years old that I was lying there in the bed talking to Dr. Chaffee saying 'I'm going to be a doctor.' That's bullshit. But those were seeds that were planted at an early age and it was a very impressionable age.

"It was something more than you would see on T.V. or read in a magazine."

It was Chaffee who recommended Stanford to Hanbery and to the boy's father, who was in the real estate and loan business in Southern California after moving the family, including Jake at age 6 months, from Enid, Okla.

A shy young man, still fighting residual symptoms of his boyhood malady, prospered at Stanford and continued on into medical school, where during his first year he decided to become a neurosurgeon.

He credits Hadley Kirkman, now an emeritus professor of anatomy, and Robert Turner for sparking his interest in "anatomy and especially in the microscopic anatomy of the central nervous system."

Hanbery reminisces fondly about Turner's neuroanatomy course and an elective exercise.

Each week, Turner would pass out a sheet of paper giving a clinical synopsis of a patient, "and then he wanted us to list all of the symptoms and then opposite each symptom to put the anatomical area of the brain or brainstem or spinal cord that would be responsible for that symptom."

-more-

The students would be expected to localize the lesion.

"It was an intellectual exercise. It was something that introduced us at a very early stage in medical school to something that related to sick people.

"I often think young medical students are eager and hungry even before they should be for clinical applications. That sort of an intellectual exercise was extremely stimulating to me. I enjoyed it thoroughly. I certainly participated in the elective part of the course and I think that was really one of things that turned me on."

Hanbery spent a year as a general surgery resident, a year in orthopedic surgery and then a year as chief general surgery resident at Stanford University Hospital.

Then in 1948, he went to the Montreal Neurological Institute, perhaps the most prestigious center at the time for neurosurgery on the North American continent.

Silverberg says Hanbery's strong clinical bias was clearly evidenced by the time he arrived in Canada.

"The man who was widely known in Montreal, who attracted top students was a man named Wilder Penfield," Silverberg says. "But Jake Hanbery most often talks about another doctor, William Cone, who was more intimately patient oriented."

Hanbery stayed in Montreal until 1954, spending his final year on the faculty, before returning to Stanford as an assistant professor in 1954.

He has remained on the faculty of his alma mater—first in San Francisco, then on the Stanford campus—ever since, except for a brief period during five years of private practice at Palo Alto Medical Clinic. (He spent most of his private practice years on the Stanford voluntary faculty).

The years, Hanbery explains, have made him contented:

"I think it was always my dream to establish a neurosurgery training program at Stanford where there had never been one. I think being able to realize that goal and the continued association with the young people is the thing that's made it so enjoyable for me."

Health Policy Conference Scheduled April 17

STANFORD—

"Making Health Policy: By Decision or Default?" is the focus of an April 17 conference open to the public in Fairchild Auditorium at the Stanfor University Medical Center.

Sponsored by the Consortium for Health Research and Policy at Stanford, in association with area Leagues of Women Voters, the conference will include lectures by eight medical experts, and 10 workshops covering various planning issues.

Speakers include Victor Fuchs, Stanford University professor of economics, discussing "**Who Shall Live** Revisited. The lecture will update Fuchs' book of approximately a decade ago.

"Amcng changes which we've perceived," said Fuchs, "is the role of the physician on the health care planning team. In my book I called him the captain. Now we are referring to the doctor as the co-captain, a role the physician shares with management."

Other speakers include Stanford University President Donald Kennedy; Ralph Schaffarzick, medical director senior vice president of Blue Shield of California and a member of the Stanford clinical faculty; Philip Lee, professor of social medicine and director of the Institute for Health Policy Studies at the University of California at San Francisco; James Fries, associate professor of medicine at Stanford and the author of a bestselling consumer health guide.

Also, Count Gibson, chairman of the department of family, community and preventive medicine at Stanford; Halsted Holman, professor of medicine; and Nathan Maccoby, director of the Institute for Communications Research at Stanford.

Among the 10 afternoon workshops are "The Educated Patient," Health Care for the Disadvantaged," "A Mental Health System: Effective and/or Affordable," "Humanistic Medicine," and "The Government as Purchaser."

Continuing education credit is available for both doctors and nurses.

who attend.

Registration payable by April 14 is $10. A box lunch is available for $5.

For further information, contact the League of Women Voters of South San Mateo County between 10 a.m. and noon weekedays, (415) 325-5780.

STUDY NEEDS VOLUNTEERS ON ORAL CONTRACEPTIVES

STANFORD—

The Stanford Heart Disease Prevention Program (SHDPP) is attempting to complete its two-year investigation of the mutual effects of exercise and oral contraceptive use on blood cholesterol levels.

The investigators are currently seeking women volunteers who are sedentary, use oral contraceptives, *and* are between the ages of 21 and 35. Participants must be non-smokers.

Testing will involve one visit to the SHDPP facilities at 730 Welch Road, where staff will draw a small blood sample, conduct a bicycle fitness test, and determine body density by underwater weighing.

Participants will receive detailed information on their blood cholesterol levels, percentage of body fat, and maximum oxygen transport capability.

Women interested in volunteering for the study should call Dan Merians at 497-6254 for further information.

WHEN STUDENT "DOCTORS" TREAT COMPUTER "PATIENTS"

STANFORD—

A Stanford project to develop a computer program for teaching medical students the diagnostic process has been awarded a two-year grant of $99,248 from the National Fund for Medical Education (NFME).

The goal of the project, says its director Dr. Roy H. Maffly, professor of medicine, is to instruct students in a "hypothesis-directed" approach to diagnosis.

"Traditionally," explains Maffly, "medical students are taught to evaluate patients by first obtaining a large body of standard information and then developing a list of possible diagnoses (hypotheses) which are then followed up by laboratory work and procedures.

"Over the past decade it has been shown that expert physicians use a quite different approach. They obtain a few pieces of important information about the patient's complaint, they develop a short list of hypotheses which can explain this information, and they then gather information based on these hypotheses—looking for evidence which supports or refutes each possibility.

"This approach is less costly and more efficient than the one most medical students are taught."

Maffly, who is director of StanMed, the Medical School's computer system for medical education, says that students' interest in computerized instruction has been growing over the past few years.

So far StanMed, which began in 1968, has offered specialized programs in such areas as physiology; physical diagnosis; water and electrolyte disturbances and treatment; primary care; gynecology and obstetrics; gross anatomy; and nephrology.

But when he applied for funding for his new project, Maffly realized it entailed an idea more ambitious than previously attempted. "This computer program would not only simulate a patient and his symptoms, as others have done before, but it would encourage students to mimic the way that a practicing physician actually arrives at diagnosis," he says.

He explains that a talented Stanford undergraduate, John Macias, has started developing a computer program for use with this approach.

"If the project is successful, a medical student will be able to sit at a terminal, be presented with a patient who has a major symptom, and develop a list of possible diagnoses. The student will then evaluate each hypothesis by "taking" a relevant history, inquiring about physical findings (like blood pressure), and requesting relevant laboratory tests and procedures.

"At selected points along the way the student will be asked to evaluate the likelihood of each hypothesis. The computer will offer advice and criticism, based on its own assessment of all the patient information both known and unknown to the student."

When the exercise is finished, he says, the computer will analyze and critique the efficiency of the student's diagnosis.

While Maffly readily agrees with the sceptics that machines cannot replace human instructors, he stresses that the use of computers in all aspects of medical education and practice is on the rise, as it probably will be for the next few decades. "Computer costs are going down as the quality of programs improves."

-more-

And he sees certain benefits in computerized instruction for the medical student, including the ability to actively "practice" medicine on a simulated patient, even before actual clinical training begins.

He says he's observed that if students' computer patients should die, for example, they take it very seriously and strive to learn where they made their mistakes. "It shakes them up, and they learn from that," he says.

Maffly also sees some benefits for the faculty members involved. "For one thing, it's very easy using these systems to gather responses from students and evaluate the overall effectiveness of the information you're presenting."

Also, he notes, because computers require definitive information and responses, the very act of writing a good program presents a challenge to the faculty person in terms of honing in on precise knowledge and theory. "When you're giving a lecture it's easier to fuzz over things you may not be quite sure about," he explains.

The real challenge for physicians, he says, is to avoid feeling threatened by the computer's potential. (That includes the type of activity Stanford's SUMEX-AIM program is involved with—the application of artificial intelligence to medicine, whereby a computer will actually aid a practicing physician in reaching a diagnosis).

Since 1975 StanMed has been incorporated in a dedicated minicomputer located at the Veterans Administration Medical Center in Palo Alto. Two microcomputers were recently purchased to expand the capacity of the system.

Students have direct access to the system via terminals in the Fleischmann Learning Resource Center. Also, any terminal with phone access may be used. (One is actually available for students to borrow and take home if they wish.) The only expertise students need is typing; no computer background is necessary.

The NFME grant, Maffly notes, will enable Stanford to purchase additional hardware, including another microcomputer.

In addition to StanMed, Stanford medical students have access to the "Health Education Network," through which students nationwide may gain access to various teaching programs by telephone. Maffly serves on the board of directors of this Network, which includes systems from Ohio State University and Massachusetts General Hospital.

"If successful our new diagnostic program can be added to the offerings of the Health Education Network, which will ensure an increasingly wide, national dissemination."

The National Fund for Medical Education is a public foundation that was chartered by Congress in 1954 to mobilize voluntary support for medical education. It has awarded over $55 million to medical schools, societies and consoria since its founding. The primary mission of the Fund is to promote the best possible health care for the American public by supporting improvements in medical education.

FOR IMMEDIATE RELEASE

PAJARO DUNES—

A deep commitment to the preservation of academic values must underlie all research agreements between universities and private companies seeking to apply the discoveries of university research, a two-day conference on biotechnology concluded on March 27.

"Agreements should be constructed, for example, in ways that do not promote secrecy that will harm the progress of science," the participants agreed.

Universities must also avoid entering into agreements that might impair the education of students, interfere with the choice by faculty members of the lines of inquiry they pursue, or divert the energies of faculty members from their primary obligations to teaching and research.

The meeting was convened by the presidents of the five leading research universities, Donald Kennedy, Stanford; Marvin Goldberger, California Institute of Technology; David Saxon, University of California; Derek Bok, Harvard; and Paul Gray, Massachusetts Institute of Technology. There were 35 participants which included faculty scientists, industry representatives, and other university administrators.

The purpose of the conference was to consider the problems that have sprung up in the relationships between industry and academe, which some fear may lead to a distortion of the purposes of the university, if not thoughtfully constructed.

"The conference made encouraging progress at defining issues and testing agreement," said Kennedy, one of the meeting's key organizers.

He stressed the meeting did not prescribe policies, but guidelines for groups and institutions that will ultimately make policy.

"We considered a range of issues," he said. "They included the importance of the field of biotechnology, the qualities of the university research enterprise that require protection, the need to develop 'intellectual property,' and the possible conflicts between that and other values and the problems associated with the undertaking of entrepreneurial roles by faculty members and the universities."

A preliminary statement given to reporters after the private conference "sketches the positions at which we arrived," Kennedy said. He stressed these ideas would be evaluated at each university, at other universities that were not represented at the meeting, and at national associations of universities concerned about these issues.

"Research of the past several decades, through enlightened public support, has profoundly advanced the understanding of life processes," began the statement. "A new biotechnology of extraordinary promise has emerged.

-more-

"While much of great importance remains to be learned at the most fundamental level about living organisms, applications of present knowledge can be foreseen that are likely to be of far-reaching benefit to people everywhere.

"These useful applications may well improve health, enhance food and energy supplies, improve the quality of the environment, and reduce the cost of many industrial processes and products."

With such beneficial possibilities at least dimly foreseeable, the participants agreed, it becomes a matter of concern to take constructive steps toward their fulfillment.

"The chain of progress from basic research to useful applications necessarily involves universities and industry," the participants said. "For the promise to be fulfilled all the links of the chain must be strong." That would require thoughtful restructuring of the relationships between academia and industry in order to transfer research results promptly into human services.

The new relationships offer, at the same time, limited assistance in returning to the universities some of the external value generated by the research of their faculties.

The conference discussed these topics, which were analyzed by smaller groups, then evaluated at Saturday's plenary session:

- The research environment in the universities has special properties that promote the quality of original work and graduate training. These include openness of communication, the freedom to choose research pathways, and faculty commitment to the primary goals of teaching and research.

These properties are important to preserve. Ways should be found to satisfy the university community and the public that agreements with industry are constructed so as not to limit openness of communication and freedom of scholarly direction, nor to deflect the energies of faculty members from their primary obligations.

- Universities are a repository of public trust and, in many cases, of public funds as well. They have an obligation to the public as well as to their students and faculty to ensure that they remain devoted to their primary goals, and that their facilities be properly used in their pursuit of these goals.

- The quality of openness in research communication has special value. Exceptions to the rule of prompt disclosure made for research agreements may entail only brief delays to allow for patent filing.

- Patent licensing programs by universities are desirable ways of promoting technology transfer and of returning value to the institution provided that steps are taken to protect the values of openness.

- Where faculty members have significant financial interest in a company, and their activities are important in the financial success of that firm, it is generally not advisable for the university to be direct investor.

The participants agreed that in many fields faculty involvement with the commercial world provides material for teaching and research, career opportunities for students, and support for institutional activities.

-more-

"Notwithstanding these benefits," the participants said, "professors' relationships with commercial firms should not be allowed to interfere with their obligation to the university to fulfill their primary responsibilities of teaching and research."

In recent years, the report noted, the problems of achieving this goal have assumed greater urgency because of the growing tendency, in the biotechnology field, for professors to own significant blocks of stock in commercial enterprises, to assist in their formation, or even assume substantial executive responsibilities.

"Conflicts of interest may arise through combinations of public funding, private consulting, and equity holding in a faculty member's area of research," the report said.

"These developments underscore the need for universities to consider the rules and procedures needed to insure that faculty members fulfill their responsibilities to teaching and research, and to avoid conflicts."

The participants agreed that universities have a responsibility of not only maintaining academic values, but also satisfying faculty, students, and the general public that they are being maintained. But they disagreed on the method by which this can be done.

"One way of accomplishing this result is to make public the relevant provisions of research contracts with industry," the report said. "Another method may be to allow a faculty committee or some other competent body to examine all research contracts with industry and assure that their terms are consistent with essential academic values."

The statement added, "Although we see no single 'right' policy, we do believe that each university should address the problem vigorously and make efforts to publicize widely and effectively the rules and procedures it adopts."

The participants said copies of applicable rules should be available to companies that hire faculty consultants, and that companies should be expected to act in conformity with these regulations.

The conference considered whether university patent programs should grant exclusive or nonexclusive licenses to companies. "Some people fear that allowing a single firm the sole right to develop a patent will necessarily remove competition, slow development of the patent or even prevent development altogether," the participants said.

"This fear is exaggerated. Although, in some cases, multiple licenses will speed development, in other cases, exclusive rights are essential if development is to take place since no firm will expend large sums for development if others can reap the fruits."

The participants said that exclusivity in certain cases is recognized under federal law. "However, when exclusivity is allowed, it should be permitted only for the interval that is necessary to encourage the desired development," they said.

At a press conference after the meeting, it was pointed out that these suggestions were not intended to encompass activities of the field of biotechnology only, but extended to "all faculty members, scientists and nonscientists alike" engaged in outside activities.

They stressed that what was produced at Pajaro Dunes was not policy, but an agenda of issues that may "be a useful framework for the development of policy."

FOR IMMEDIATE RELEASE
STANFORD—

The traditions of open research should apply to corporate-sponsored projects on campus, executives from nine firms agreed Saturday, March 27, with the presidents of five major universities.

The executives, drawn mainly from companies active in biotechnology, were invited to a three-day private session at Pajaro Dunes by the presidents of Stanford, Harvard, MIT, the University of California and California Institute of Technology.

Patent licensing and professorial conflict of interest were the toughest issues discussed, President Donald Kennedy of Stanford told a news conference Saturday.

"There was much less fundamental disagreement than might have been supposed" at the outset, Harvard President Derek Bok said.

Except for brief periods when patents are pending, he said, "there was no dissent from anyone" that "secrecy should be ruled out" in any corporate research on campus.

UC-Berkeley Chancellor Ira Hayman was "surprised at the unanimity" that "the doctrine of trade secrets should play no part in the research process" on campus.

Syntex Corporation President Albert Bowers said secrecy concerns had been "blown up out of proportion." Author of 90 scientific papers and holder of 120 patents, Bowers said any delays resulting from patent applications should be a matter of "days or weeks, not months or years."

UC President David Saxon said universities are "extremely unhappy" with federal agency contracts which may result in "substantial delays" of "months" in publication, although these provisions are "rarely invoked."

Bok said: "I'm considerably more concerned about secrecy restrictions being advanced by the government" than from business.

Where a university might decide against a particular corporate proposal, "if you're going to do any science at all, you're going to have to deal with the government. Their power is much more pervasive.

"To the extent that they begin to say foreign nationals can't come in classrooms or seminars. . . or that information is 'born secret,' that raises much larger problems for science."

Saxon said it was "ironic" that in its groping for policy in this area, the government is "as much conerned about Japan as it is with the Soviet Union."

Reporters, representatives of the Natural Resources Defense Council, and graduate students at Stanford all asked that the Pajaro conference be open to them. Two business participants in the new conference, Bowers and Applied Biosystems President Sam Eletr, indicated the discussion would not have been inhibited by the presence of the press. Kennedy, who convened the group, felt it would have been "somewhat more difficult" to reach agreement with a large audience.

Kennedy said he had "no objection in principle" to helping the NDRC contact possible funding sources for public conferences on the same subject, but felt it might be "more valuable" to have other groups besides those at Pajaro Dunes brought into the dialogue. "After all, our work product is out there," he explained.

-more-

Kennedy told reporters that while participants "concur overwhelmingly with the statement," each remained free to agree or disagree on specific points.

Participants included:

Stanford: Donald Kennedy, president; Lawrence Crowley, vice president for medical affairs; Robert Rosenzweig, vice president for public affairs (conference organizer); Gerald J. Lieberman, vice provost and dean of research and graduate studies; Charles Yanofsky, professor of biological sciences; Channing Robertson, professor of chemical engineering; Robert Swanson, president, Genentech; and Albert Bowers, Syntex Corporation.

Massachusetts Institute of Technology: Paul Gray, president; Francis Low, provost; Kenneth A. Smith, associate provost and vice president for research; Michael L. Dertouzos, professor of electrical engineering and computer science, and director of the Laboratory for Computer Science; Phillip A. Sharp, professor of biology; Robert A. Charpie, president, Cabot Corporation; and David I. Kosowsky, president, Damon Corporation.

Harvard: Derek Bok, president; Henry Rosovsky, dean of the College of Arts and Sciences; Daniel Steiner, general counsel; Daniel C. Tosteson, dean, School of Medicine; David Hamburg, professor of health policy; Colman Mockler, Jr., president, Gillette Corporation; and Francis H. Burr, fellow of Harvard College.

California Institute of Technology: Marvin Goldberger, president; John Roberts, provost; Donald Fowler, general counsel; Fred Anson, profesor of chemistry and chairman of faculty; Norman Davidson, professor of chemistry; Sam Eletr, president, Applied Biosystems, Inc.; and William Simeral, Vice President, E.I. Dupont de Nemours, Inc.

University of California: David Saxon, president; Ira M. Heyman, Chancellor, UC-Berkeley; Robert Sinsheimer, Chancellor, UC-Santa Cruz; Julius R. Krevans, dean, School of Medicine, UC-San Francisco; William Rutter, professor, biochemistry and biophysics, UC-San Francisco; Paul Boyer, professor of chemistry, UC-Los Angeles; and Ronald Cape, chairman and chief executive officer, Cetus Corp.

Invited Guests: Robert Glaser, president, Henry J. Kaiser Family Foundation; William Phillips, professor and chairman of chemistry, Washington University; and Arnold O. Beckman, chairman of Board, Beckman Instruments, Inc.

INTERFERON HELPS REDUCE COMPLICATIONS OF CHICKEN POX IN CHILDREN WITH CANCER

EDITORS: Advance embargoed for release until Thursday AM April 1 to coincide with publication in *The New England Journal of Medicine.*

STANFORD—

Interferon effectively reduces life-threatening complications of chicken pox in children who have cancer, according to a recent study led by researchers from Stanford University School of Medicine and published in the April 1 issue of *The New England Journal of Medicine.*

The study, conducted in pediatric patients at the Children's Hospital at Stanford, St. Jude Children's Cancer Research Hospital in Memphis, and by physicians in the Children's Cancer Study Group (a national group that aims to standardize treatment of childhood malignancies), is a first step toward establishing interferon's usefulness as a chicken pox remedy for people who develop a severe case of the disease, said Dr. Ann Arvin, assistant professor of pediatrics at Stanford.

Chicken pox is a common and highly contagious childhood disease caused by the *Varicella* virus. It is a relatively benign illness and requires no more than careful home treatment in the majority of patients. But under some circumstances the disease becomes a serious and life-threatening infection, and for these cases, an effective drug treatment is badly needed, Arvin explained.

For instance, people whose natural disease-fighting defense (immune system) is out of commission are at high risk for developing a severe case of the rash-producing disease.

Children with cancer, whose disease is treated with anti-cancer drugs or radiation that also suppress the immune system, are particularly vulnerable.

Over 30 percent of children undergoing anti-cancer therapy who contract chicken pox may sustain life-threatening spread of the disease—often leading to pneumonia or hepatitis— and as many as ten percent may die. It is for this reason that Arvin and her associates, Drs. Joseph Kushner, Sandor Feldman, Robert Baehner, Denman Hammond and Thomas C. Merigan, performed the research in pediatric cancer patients.

In 44 children with varying types of cancer who also came down with chicken pox, interferon therapy was administered to 23, while a harmless placebo was given to 21. The trial was divided into two phases, with some of the interferon-treated children receiving higher doses of the natural virus-fighting substance than others.

After seven days, 90 percent of the interferon recipients had been free of new rashes and spread of disease for at least a day, as compared with 56 percent of the placebo recipients.

In the higher-dose phase of the trial, after six days, 92 percent of the interferon recipients showed no new evidence of spread of disease for at least a day as compared with 45 percent of placebo patients.

-more-

Overall, the incidence of "fatal and life-threatening varicella was 8.6 percent (two of 23) in the interferon group and 28.6 percent (six of 21) in the placebo group," the researchers reported.

"Our study showed that intramuscular interferon could be safely administered to immuno-compromised patients with varicella (chicken pox) on an outpatient basis," they added. "With the availability of large quantities of interferon from new sources, its use for the treatment of varicella and herpes zoster (shingles-- another form of disease caused by the same virus) in high-risk patients has become practical."

A case of chicken pox usually erupts in an unvaccinated patient about three to seven days after exposure to the virus. A severe case, if untreated, may involve spreading viral infection in the lungs, the liver and the brain five to seven days after the initial rash, fever and other common symptoms first appear.

Currently, the only treatment for chicken pox is a preventive one—an immune globulin that must be injected very shortly after the person is exposed to the virus. But "varicella develops in many children without an identified exposure," the authors pointed out, leaving immuno-compromised patients at high risk if their exposure to the disease goes undetected.

Right now, the researchers are continuing to investigate interferon therapy in immune-weakened children with cancer because they are the most susceptible to damaging or deadly complications of the disease.

Before biosynthetic interferon could be used routinely to treat chicken pox, Arvin said, its side effects must be carefully documented. Even if the side effects are minimal, its use would best be restricted to those likely to have serious complications. And, thus far, there is no way of predicting, except in immune-weakened patients, who is in this high-risk group, Arvin said.

The type of interferon used in these studies was derived from human blood cells, or leukocytes. The amounts if this substanace available for clinical testing have been minute and extremely costly.

But the growing recombinant DNA industry is churning out biosynthetic interferon at much lower cost, making the prospect of interferon therapy more practical for a variety of diseases.

Even so, "prevention of the infection must be the goal for the management of varicella in children at high risk," the authors cautioned.

"Although treatment with interferon and other antiviral agents benefits immuno-compromised patients with varicella, it is likely that this primary systemic viral infection will continue to cause morbidity and mortality in some patients," they wrote.

"In addition to zoster immune globulin and varicella vaccine, antiviral agents may have a role in preventing varicella when they are given during the incubation period to children whose exposure is identified too late for protection to be provided by the administration of passive antibody," the researchers concluded.

"HONEYMOON" IS OVER FOR INTERFERON

EDITORS: ADVANCE FOR RELEASE FRIDAY MARCH 26, TO COINCIDE WITH PUBLICATION IN *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.*

STANFORD—

Interferon trials in human patients are entering a new phase, according to Dr. Thomas Merigan, a pioneer in interferon research at Stanford University School of Medicine.

Now that the "honeymoon" is over and people are no longer expecting magical cures from the highly publicized substance, the long hard work of establishing interferon's usefulness in therapy has begun, Merigan said.

What makes interferon's future bright, Merigan said, is that the previously rare and precious protein is becoming inexpensive and widely available through recombinant DNA techniques. And it has now been confirmed that the recombinant DNA-produced substance has properties nearly identical to those of the naturally derived protein.

"It's disappointing to some, but not surprising to those of us who work in the field, that interferon will not bring miracles as some people once hoped," Merigan said. "However, we are optimistic about the medical potential for interferon. Now we can seriously begin to study the material with the knowledge that there will be plenty available to treat patients in whatever diseases it may prove useful," Merigan observed.

Results from one of the first trials of gene-spliced interferon were published by Merigan and colleagues Sandra Horning, Jedd Levine, Richard Miller and Saul Rosenberg in the March 26 issue of the *Journal of the American Medical Association.*

In a "phase I" trial designed to determine toxicity and pharmacokinetics, monitor side effects and determine tolerable doses of the "cloned" substance in cancer patients, the researchers found that the properties of biosynthetic interferon did not differ significantly from those of the natural protein. (Even the side effects—which are mild compared to many conventional anti-tumor methods—mimic those of the natural substance. They include fever, headache, muscle ache, fatigue and nausea.)

-more-

(Horning presented pre-publication results of this study October 1981 in San Francisco at a meeting of the International Congress for Interferon Research.)

The new era of interferon testing will translate the discovery of interferon's biologic activities into effective medications through rigorous controlled "phase III" trials, Merigan explained.

(In the complex new drug evaluation process, a phase I trial is designed to measure toxicity, side effects and dosage ranges; phase II trials measure how effectively the drug combats disease; and phase III trials provide data about the drug's long-term effects and abilities to counteract disease in comparison to other therapy.)

Other recent work by Merigan and colleagues has paved the way for just such a definitive trial of interferon in patients with chronic hepatitis B infections, he noted. A second *JAMA* paper, to be published in a later issue, will report on a phase I pilot program of administering interferon and another drug, adenine arabinoside monophosphate (ara-AMP), to hepatitis sufferers.

"Currently there is no proven treatment for chronic hepatitis," Merigan said. "Based on results from this pilot study where interferon/ara-AMP therapy seems to work, we feel further testing is clearly worth while in a controlled clinical study with large numbers of hepatitis patients."

Merigan's colleagues on the study are Drs. Coleman Smith, Lynn Kitchen, George Scullard, William Robinson, and Peter Gregory.

(The phase III trial, which will last about five years, still has openings for volunteer hepatitis patients who are urged to call 415: 497-5315 if they wish to participate in the trials free of charge.)

Merigan and his colleagues in oncology, Drs. Horning and Rosenberg, are also planning a phase III study in cancer patients, specifically individuals with a form of lymphoma, a cancer of the lymphatic system.

In recent phase I and phase II testing, interferon has been observed to shrink lymphoma tumors in some patients, Merigan pointed out. The phase III study being put together at Stanford will test the ability of interferon combined with conventional chemotherapy methods in controlling lymphomas.

Phase III trials such as these generally take five years or more, Merigan explained, because the long term effects must be examined. In the case of hepatitis patients, the substance's long term effects on liver disease and prevention of liver cancer are of concern and for patients with non-Hodgkin's lymphoma, the recurrence of tumors and mortality must be determined, he said.

-more-

"We believe that the eventual niche for interferon in cancer therapy will be found in combination with other agents," Merigan said.

He stressed that basic investigations into how interferon works must continue along with clinical work.

"We can only fully exploit the clinical potential of the interferon system against disease if we also have much greater understanding of its mechanism of action and method of production," he stated.

A few things are already known about the way in which interferon works, Merigan reported, but much more remains to be uncovered.

Two primary activities of the substance are enhancement of the body's own immune system and a slowdown or halt in cell division in those tissues treated with interferon. (There is some evidence that the anti-proliferative effect may be accomplished through inhibition of DNA synthesis, he said.)

Both of these activities play a role in interferon's therapeutic effects, Merigan believes, but research has not yet sorted out the contributions of each.

Another yet to be solved riddle is why the body produces so many different types of interferon—at least 15 at present count—and what accounts for their varying potency against different types of disease.

"We don't yet know why there are different types—but once we know their functions, we can start to determine which is the best type of interferon to use for any particular disease," Merigan said.

This is where basic research could speed up the clinical side, Merigan said. The laborious process of testing each type of interferon in a lengthy trial against each conceivably treatable disease could be short-circuited by learning the biological basis for how interferon works, he explained.

Basically, three different classes of interferon (leukocyte, fibroblast and immune) are produced by their respective cell types, and each class consists of several sub-types with slightly differing chemical structures.

It seems likely that malignancies and diseases would be most effectively subdued by the type of interferon produced in cells most closely associated with the diseased tissue, Merigan said.

There is already evidence, he noted, that tumors of the blood are more responsive to leukocyte interferon and solid tumor cell lines in tissue culture are most sensitive to fibroblast interferon.

In some cases the different interferons operate synergistically, two or more together having a greater effect than expected, Merigan said.

A newly discovered type of interferon, known as gamma, is particularly intriguing. Chemically it is quite different from all other interferons and appears to interact with receptors on the cell surface in an entirely unique way, Merigan said. Its early clinical testing is just now beginning.

Viral diseases that have already shown some promise for treatment by interferon are conditions such as herpes zoster, herpes simplex, cytomegalovirus, rabies, and chicken pox; Merigan and colleagues are also examining interferon's ability to prevent spread of disease in patients whose immune systems are suppressed, such as those who have received organ transplants or who receive cancer-fighting immunosuppresive therapy.

Even multiple sclerosis is being studied for potential response to interferon.

At Stanford, malignancies currently under study with interferon include breast cancer, nodular lymphoma, nasopharyngeal cancer, and Kaposi's sarcoma.

Ultimately, interferon likely will be most useful in suppressing and treating certain types of chronic viral infections (such as hepatitis B), in supplementing conventional anti-tumor methods in certain types of cancer, and in controlling or preventing some acute viral diseases (such as the common cold), Merigan predicted.

"But there's still a long road ahead for the patient who is afflicted with one of these diseases," Merigan emphasized. "Right now, we can only consider interferon as a compound with biologic activity. Until it's completely confirmed in rigorous tests to extend life or to extend the disease-free interval, we just don't have sufficient assurance to promise effective interferon therapy for any disease."

NUTRITIONIST SAYS DIET IS CONSTANT LIFE-AND-DEATH MATTER FOR KIDNEY PATIENTS

STANFORD—

Registered dietician Janet Cecchino, of Stanford University Hospital, can't think of an area where nutrition plays a more critical role in overall medical care than in the treatment of kidney disease.

That's why she chose, while completing her degree at U.C. Davis several years back, to specialize in the field of renal nutrition.

"I felt it was the area where I could do the most," she says, explaining that her patient load at Stanford's Dialysis Center is usually between 35 and 50 at any time.

Her patients, says Cecchino, fall into two categories of renal disease. With chronic renal disease, there is a slow loss of kidney function over months, years, or even a lifetime.

With acute renal failure, says Cecchino, there is a sudden shut-down of kidney function within a matter of days. This is usually caused by physical trauma or stress.

"In these cases," says Cecchino, "the kidneys will usually return to functioning within several weeks."

Healthy kidneys excrete all the waste products of the body and regulate salt and water balance, acid-base balance, and other body functions, explains Cecchino.

"They also produce a hormone which stimulates red blood cell production, and convert vitamin D to its active form.

"Renal failure occurs when all of these processes either stop, or drop to a minimum level not compatible with life."

The way a dialysis machine works is to circulate the patient's blood through an artificial kidney, where waste products are removed by diffusion into a washing solution.

"But the machine is not a replacement for a kidney," says Cecchino. "There are still certain things it won't do."

For one thing, she points out, real kidneys function 24 hours a day seven days a week, whereas patients undergo dialysis only three times a week, for three to five hours each time.

Therefore, the day or two in between dialysis sessions is a crucial time for patients, Cecchino says. If they neglect the guidelines of their special diets, they may gain lots of weight or attain dangerously high potassium levels.

The three key requirements of her patients' diets, says Cecchino, are: to restrict salt (sodium) intake; to restrict potassium intake; and to restrict liquid intake depending on how much urine is passed.

"My whole job at the Dialysis Center, really, is to counsel and educate patients so they stick to their diets."

To avoid salt, she says, kidney patients are not supposed to eat commercially prepared Chinese food, Italian food, Mexican food, excessive cheese, canned vegetables, canned soups, or salty snack foods.

A potassium level which gets too high can lead to cardiac arrythmias (irregular heartbeats) and eventual cardiac arrest. And potassium is found mostly in many fruits and vegetables—foods Californians love to eat, notes Cecchino.

-more-

Kidney patients, she says, are always on large doses of vitamin B (folic acid) as well as a multivitamin, in order to supply nutrients left out of their meals and replenish those lost to dialysis.

One cause of chronic renal failure, says Cecchino, is hypertension. To control it is an important prevention measure. Another condition leading to such problems is diabetes. In some cases, a predisposition for kidney disease is inherited. "And in other cases we don't know what caused it."

For the more than 50,000 Americans on dialysis today, says Cecchino, an increasing worry is bone disease as longer survival becomes common with the new technology.

"Their kidneys are not producing the active form of vitamin D, a requirement for healthy bones." Luckily, she says, there are now several types of vitamin D preparations on the market which are given to long-term kidney patients.

Another problem affecting bones, says Cecchino, is an overaccumulation of phosphorus in the blood which binds to the person's calcium supply, in the long term creating a calcium deficiency and a resultant overactivity of the parathyroid gland.

This is why most of Cecchino's patients, she says, take phosphate "binders" with their meals, and/or decrease their intake of milk and dairy products.

How well do Cecchino's patients follow her instructions?

"I get frustrated a lot," she concedes. "I have probably fewer than 10 patients who comply with everything in their diets."

As a result, she says, her job entails a lot of repetition each month when the patients have blood work at the lab.

Some of her dialysis patients, says Cecchino, have had kidney transplants at Presbyterian or U.C. San Francisco Medical Center. The surgical procedure involves transplanting one kidney either from a cadaver or a family member of the patient.

Those who have successful transplants, says Cecchino, still face dietary restrictions, mainly due to the side effects of steroids they take to prevent rejection.

Besides her work at the Dialysis Center, Cecchino sees patients at the renal clinic Wednesday mornings. "These people have varying degrees of renal insufficiency, and many are already on special diets." It's been shown, she says, that a rigorous restriction of protein intake can often slow the progression of renal failure.

Nobody yet knows, says Cecchino, how long a person can live on dialysis, since the treatment has been available for only about 20 years. Some patients so far have survived for that long.

Cecchino received her training in renal nutrition during a graduate internship at the Ruth Presbyterian St. Luke's Medical Center in Chicago.

She has been at SUH for two and a half years, where before serving as renal nutritionist she worked in general medicine. Even now, Cecchino really has two positions, working part-time with surgery patients. "But renal nutrition is my true love," she admits.

Cecchino is a member of the National Kidney Foundation, which has a section called the Council on Renal Nutrition.

She is now busy as publicity and fund raising chairperson for a scientific meeting of the Council, on the medical and nutritional management of renal disease, to be held in San Francisco this June.

NUTRITIONIST SAYS DIET IS CONSTANT LIFE-AND-DEATH MATTER FOR KIDNEY PATIENTS

STANFORD—

Registered dietician Janet Cecchino, of Stanford University Hospital, can't think of an area where nutrition plays a more critical role in overall medical care than in the treatment of kidney disease.

That's why she chose, while completing her degree at U.C. Davis several years back, to specialize in the field of renal nutrition.

"I felt it was the area where I could do the most," she says, explaining that her patient load at Stanford's Dialysis Center is usually between 35 and 50 at any time.

Her patients, says Cecchino, fall into two categories of renal disease. With chronic renal disease, there is a slow loss of kidney function over months, years, or even a lifetime.

With acute renal failure, says Cecchino, there is a sudden shut-down of kidney function within a matter of days. This is usually caused by physical trauma or stress.

"In these cases," says Cecchino, "the kidneys will usually return to functioning within several weeks."

Healthy kidneys excrete all the waste products of the body and regulate salt and water balance, acid-base balance, and other body functions, explains Cecchino.

"They also produce a hormone which stimulates red blood cell production, and convert vitamin D to its active form.

"Renal failure occurs when all of these processes either stop, or drop to a minimum level not compatible with life."

The way a dialysis machine works is to circulate the patient's blood through an artificial kidney, where waste products are removed by diffusion into a washing solution.

"But the machine is not a replacement for a kidney," says Cecchino. "There are still certain things it won't do."

For one thing, she points out, real kidneys function 24 hours a day seven days a week, whereas patients undergo dialysis only three times a week, for three to five hours each time.

Therefore, the day or two in between dialysis sessions is a crucial time for patients, Cecchino says. If they neglect the guidelines of their special diets, they may gain lots of weight or attain dangerously high potassium levels.

The three key requirements of her patients' diets, says Cecchino, are: to restrict salt (sodium) intake; to restrict potassium intake; and to restrict liquid intake depending on how much urine is passed.

"My whole job at the Dialysis Center, really, is to counsel and educate patients so they stick to their diets."

To avoid salt, she says, kidney patients are not supposed to eat commercially prepared Chinese food, Italian food, Mexican food, excessive cheese, canned vegetables, canned soups, or salty snack foods.

A potassium level which gets too high can lead to cardiac arrythmias (irregular heartbeats) and eventual cardiac arrest. And potassium is found mostly in many fruits and vegetables—foods Californians love to eat, notes Cecchino.

PAJARO DUNES PRESS BRFIEFING SATURDAY, MARCH 27

Science writers/editors:

Last month, Stanford University announced that the presidents of five major research universities would meet privately this week with their counter parts from several high tech firms as well as faculty members to hammer out suggestions for guiding the complex relationships that have sprung up between industry and academe. The meeting, organized by the presidents of the University of California, Caltech, rvard, MIT, and Stanford, will be held in Pajaro Dunes on the Monterey Peninsula.

Because of a high-level of media interest in this meeting and in accordance with our earlier intentions, we have scheduled a press briefing at the end of the conference to discuss whatever conclusions the participants may reach.

The briefing will be **2 p.m. Saturday, March 27 in Pajaro Dunes.** Stanford University President Donald Kennedy and Public Affairs Vice President Robert Rosenzweig will be available to discuss the meeting and answer questions. Other attendees who wish to meet with reporters have been asked to join.

STANFORD—

New medical treatments often are denied to the public or provided at inflated costs because of flaws in the way health care is evaluated nationally, a Stanford University researcher has concluded.

To remedy the problem, Dr. John P. Bunker and his colleagues have proposed that a non-governmental Institute for Health Care Evaluation (IHCE) be established to unravel whether a particular treatment, for example, is a cure, an experimental effort, or even fraud.

Bunker is a professor of family, community and preventive medicine and director of the division of health services research at Stanford. His health evaluation blueprint was set forth in a two-part series appearing in the March 11 and 16 issues of *The New England Journal of Medicine* and was based on a report submitted to the Congressional Office of Technology Assessment.

Co-authors of the articles were Jinnet Fowles, PhD, a communication specialist in Bunker's division of health service research; and Dr. Ralph Schaffarzick, medical director of Blue Shield of California and a member of the Stanford clinical faculty.

"The absence of a consistent and explicit policy for reimbursement for new technologies results in the escalation of charges and at the same time provides incentives to conceal innovations," the authors concluded in the second article.

In addition, since there is no clearing house for evaluating new procedures, there is no consistent basis for insurance carriers, doctors or the public to learn whether a new technique, drug or other innovation is effective, he said.

Currently, experimental procedures—those whose outcomes are truly unknown—are generally not covered by private or other non-governmental insurance carriers. Therefore, doctors are given an incentive to disguise new techniques when submitting claims, the authors contend. For example, doctors performing an experimental procedure might submit an insurance claim for a similar but more conventionally accepted procedure.

-more-

Computerized billing codes, Bunker contended, also tend to discourage realistic categorizing, since doctors may tend to lump innovative procedures into outdated and oversimplified preexisting codes.

The lack of a review process has caused other difficulties. Medical fees have escalated as a result of physicians submitting larger bills for new procedures—which may be simpler and less costly than the treatments they replace.

The authors have proposed that the new institute should be managed by representatives of academic and practicing physicians, health care insurers, the government and the public, including representatives of employer and employee groups.

The institute would try to fulfill four major objectives:

•Development of a uniform data base — So that treatment data can be analyzed, the institute would need to develop guidelines for filling out patient evaluation forms. Data would be stored locally and made available anonymously to ICHE researchers.

•Authority to serve as a clearinghouse for innovation — The institute would have the authority to survey professionals to learn about proposed or needed innovations in their fields.

•Participation in clinical trials or retrospective studies — "Clinical trials, although complex, time-consuming, and resource-intensive, remain our best method of determining the relative values of alternative medical technologies," the authors said. The current number of trials, often funded by the National Institutes for Health, is too small to serve the needs of change, the article contended.

•Returning results back to participants — The medical community and public would need to acquire the data generated by the ICHE in order to make innovations.

Bunker recommended that ICHE be a nonprofit group funded by insurance carriers through voluntary contributions.

The need for the group is more urgent, the article contended, now that federal sources of health care planning funds may be drying up as part of a general federal cutback.

STANFORD—

Dr. Bruce A. Reitz has been appointed professor and director of the division of cardiac surgery at the Johns Hopkins School of Medicine effective June 1.

Reitz, recently promoted at Stanford to associate professor of cardiovascular surgery, will also serve as chief of cardiac surgery at Johns Hopkins hospital.

Dr. Norman Shumway, Frances and Charles Field professor of cardiovascular surgery and chairman of the department of cardiovascular surgery at Stanford, said in a statement, "Johns Hopkins is gaining a fine surgeon and an excellent academician. We will miss Dr. Reitz, but it is gratifying for us to see such worthy faculty members being given an opportunity to take charge of cardiovascular surgery departments at institutions elsewhere."

Shumway noted that Stanford-trained faculty members have gone on to direct at six cardiovascular surgery programs at major medical institutions throughout the nation and overseas.

The heart-lung transplant program will continue at Stanford under the direction of other faculty members, Shumway explained.

Hopkins said a search team unanimously recommended Reitz to replace Dr. Vincent L. Gott, who has headed Hopkins' cardiac surgery division since it was established as a separate division in 1965. Gott has asked to be relieved of his administrative duties but will continue his surgery and clinical research, Hopkins announced.

Reitz, 37, was appointed assistant professor of cardiovascular surgery at Stanford in 1978. A native of Seattle, he received his M.D. degree at Yale in 1970. He served his residency at Stanford from 1974 to 1978, including a tour as chief resident in the cardiovascular surgery program.

In addition to transplantation, Reitz' clinical interests include general cardiothoracic surgery with a special interest in pediatric cardiac surgery.

Reitz will be joined at Johns Hopkins by Dr. William A. Baumgartner, 34, who will become an assistant professor of cardiac surgery. Baumgartner, currently a clinical assistant professor of cardiovascular surgery at Stanford, served as chief resident in cardiovascular surgery at Stanford in 1977-78 and chief resident in general surgery in 1980-81.

He is a graduate of the University of Kentucky Medical School.

VOLUNTEERS NEEDED FOR DIABETES STUDY

STANFORD—

Volunteers are needed for a study designed to determine if the abnormalities associated with adult-onset diabetes can be corrected with insulin treatment. This research is being conducted in the Stanford University Clinical Research Center, under the direction of Dr. Gerald M. Reaven, professor of medicine, and associates.

The goal of the study is to determine if optimum diabetic control with insulin will improve the insulin sensitivity and lipid abnormalities in patients with adult-onset diabetes. To eliminate much of the trial and error in establishing the optimum daily insulin dose, a non-implantable artificial pancreas and a new portable pump system will be used to exactly determine each patient's daily insulin requirements.

Participants will administer their own insulin as outpatients for a period of six weeks and then be retested. Subsequent treatment will be evaluated individually and may include diet, oral medication, or insulin therapy.

Prospective participants must have adult-onset diabetes. They should never have been on prolonged insulin treatment, and be no more than 25 percent overweight. Volunteers accepted into the study will receive a complete medical examination including laboratory tests, dietary consultation, and education in diabetes management.

During the study, insulin and syringes will be provided. The program requires approximately 14 days of hospitalization within the six-week study period. No charges will be made to participants.

Anyone interested or wishing further information should call Dr. Michael Greenfield or Dr. Claude Lardinois at 858-3933, 9 a.m. to 5 p.m.

STANFORD TO EXPAND CANCER RESEARCH AND SERVICE CAPABILITIES

STANFORD—

Stanford University Hospital has been granted its first Certificate of Need (CON) by the state of California, for a $2,900,000 project to upgrade and expand its radiation therapy service capabilities.

The project, first recommended for approval by the Santa Clara County Health Systems Agency in January, involves aquiring two new linear accelerators—the high technology radiation equipment used in cancer treatment—and a multi-purpose simulator, which serves as a computerized guide for this treatment.

The CON, issued late last month, is the state's approval to go ahead with the project. A CON is required only for capital expenditures of over $400,000 or renovations over $600,000, or when a special service such as radiation therapy is involved, explains Ron Hill, assistant director of SUH and director of Health Services Planning. The idea behind the 1976 federal legislation requiring CON review, he says, is to promote cost containment in health care.

"Basically," he says, "we argued the special needs and circumstances of a tertiary care, teaching institution which is also an international cancer research center."

(A CON was never required at Stanford before, he explains, because of the non-reviewable nature of earlier projects and the existence of a special "certificate of exemption" which covered the entire Phase I building.)

Currently, says Hill, the Hospital has three low energy linear accelerators. The approved project will bring the number up to four by allowing the Hospital to replace one of the existing machines with a new low energy accelerator, as well as to acquire an additional more powerful, medium energy accelerator with electron beam capability for use with special cancer cases. Also, the simulator currently used with the obsolete accelerator will be replaced.

Therefore, the project is both a replacement and addition to the existing Radiation Therapy Division, headed by Dr. Malcolm Bagshaw, professor and chairman of Radiology.

A fourth specially shielded vault will be built in existing departmental space to house the medium energy accelerator, while the other new equipment will be accommodated without necessity of major remodeling.

Now that the CON has been granted, says Hill, the construction packet is being put out to bid. "We've already made some progress looking for architectural firms and structural engineers."

The new linear accelerators will be purchased from Varian Associates, and the simulator from a Canadian company.

The hope in having a medium energy (20 megavolt) accelerator, says Hill, is to not only increase patient care potential, but also facilitate certain research projects in the Division of Radiation Therapy.

NEW HOSPITAL UNIT WELCOMED AS CORNERSTONE

STANFORD—

A new unit for patients with compromised immune systems, who need special protection from exposure to germs and other harmful particles, has been opened at Stanford University Hospital.

Called the "compromised host unit," it includes six private rooms on the Hospital's east wing. The rooms, equipped with filtering systems to provide an extra clean environment, will be used mainly by patients with acute myeloid leukemia who are especially susceptible to infections, and by future patients of a planned bone marrow transplantation program, to be launched at Stanford in the near future.

Dr. Stanley L. Schrier, professor of medicine (hematology) and chief of the Division of Hematology, first suggested such a unit in 1974. He explains that acute myeloid leukemia is a devastating form of cancer, often requiring 30 to 36 days of hospitalization in isolation, and posing a great risk of death.

"It wasn't until the late 1960s or early 70s that certain effective drugs became available, but unfortunately both the treatment and the disease cause these patients to be immunocompromised."

Their immune systems are not good at fighting off infection, he explains, because their white blood cell count is "unbelievably low."

According to Dr. Kenneth Melmon, professor and chairman of the Department of Medicine, the compromised host unit is "also a cornerstone in our plans for bone marrow transplantation, since patients in that type of program are almost all compromised hosts."

He says, "Such a program could not exist without a unit such as this. And an institution like Stanford should not be without such a program."

Speaking at a March 11 open house, Schrier said, "This unit is designed for patient comfort, to provide a nourishing, favorable environment for them and their families."

He also pointed out, "I think it's a success largely because clinical faculty from the University have worked very closely with the Hospital on an identified goal. We all had to work hard and make the necessary compromises."

The unit will make use of such techniques as the filtration system mentioned above, rigorous hand washing, and slightly positive air pressure (to direct air flow away from patients). Richard Booth of Medical Center Facilities was project director of the necessary renovation, which began last August.

Anna Olsen, R.N., will be clinical nursing coordinator of the compromised host unit, which will be staffed by nurses with specialized training and two medical directors yet to be named.

Olsen attested, "It's really been difficult for us to take care of these patients in the past. This new environment should make it possible for all health professionals to work together as a team."

The station support space is not yet ready, she said, while the solarium is still being planned as a comfortable area for family members. Three of the patient rooms are already occupied, and the unit is functioning with the temporary help of the East 1A support station.

Judy Lanigan, R.N., assistant director of Nursing for medical/pediatrics, thanked the surgical region for housing displaced patients during the period of unit renovation.

SPECIAL GROUP FOUND TO INCREASE MORALE AND COOPERATION AMONG HEALTH PROFESSIONALS

STANFORD—

Like in many high-powered and stressful hospital units, the doctors in the Stanford University Hospital intensive care nursery often complained about their nurse colleagues to the director, Dr. Philip Sunshine.

And not surprisingly, nurses there voiced a seemingly equal volume of complaints about the doctors they worked with to their supervisor, clinical nursing coordinator Kathi Palange.

"Dr. Sunshine and I really got tired of talking to each other about second-hand complaints," says Palange, so last summer the two organized a nurse-physician group for the airing of grievances and problems.

Informally led by the unit's social worker Charlene Canger, the group sessions represent a new, structured beginning for a project first attempted in the mid 1960s.

Explains Sunshine, "The need for group discussions was recognized back then, specifically during a maternal/infant interaction study in the nursery, when misunderstandings developed with the nursing as well as the medical staff."

The study, he says, involved allowing mothers into the nursery for a four-month period to help care for their infants. This was followed by another four-month period without mothers being allowed in the nursery.

"We wanted to see if letting a mother in would lead to increased risk or danger to her baby, or if, by contrast, it would foster healthier psychosocial bonding between the two."

When researchers discovered a sort of competition developing between mothers and nursing staff to care for the babies, they decided to initiate discussions with the nurses, recalls Sunshine. At first, he says, the sessions were meant to resolve the specific problem at hand and to request the nurses' help in gathering data.

"But naturally, people started talking about other things, including ethical issues and staff problems." Psychiatrist P. Herbert Leiderman conducted the sessions for about two years, until then unit social worker Rose Grobstein took over.

The "Rose meetings," as they were called, comprised a loosely structured program—at times scheduled, at times specially called to deal with a crisis situation.

Grobstein, presently chief pediatric social worker at the Hospital, says that while there was never a strict agenda, often specific patient cases were discussed in depth by the nursing staff, house staff, and faculty physicians present.

Says Sunshine, "We discussed issues like how to go about discontinuing care when there was no hope for a baby; and how to communicate with community physicians and parents."

One crisis he recalls happened about three years ago, when nurses felt there weren't enough doctors on call at night to deal with more and more sick infants.

"We tried to remedy this by having the attending physician or the neonatology fellow conduct rounds at 10 p.m. But it wasn't enough."

Finally, he says, the Hospital arranged to have one extra resident each night in the nursery. And their necessity made clear, the group sessions continued on a regular basis until managerial and staff changes in the nursing program forced an extended interruption.

-more-

Now the group meets monthly, and both Sunshine and Palange are enthusiastic that similar inter-professional groups could be productive throughout the Hospital, particularly in intensive care units where tensions may run highest.

Sunshine says the program "has been fantastic" at ironing out differences, but requires an adjustment by the faculty, graduate fellows and housestaff.

"It's really threatening to the younger physicians, because the nurses are telling them when they screw up... The only way it's going to work is if the senior faculty are actively involved in the discussions," he says, indicating that so far they have been.

Palange says the dialogue has helped reduce the feeling that nurses and doctors are in two separate camps.

"It's shown through discussion that nurses are different from one another, and doctors are different from one another, too.

"... It's really made a difference in the general morale of the unit, since it's shown there is an alternative to having physicians go into their own group to gripe and nurses grumbling to each other."

She adds, "We've seen the dialogue which is begun in meetings carry on throughout the month."

(The sessions, of course, supplement the regular nursing staff meetings and management meetings where, says Sunshine, problems can often be "nipped in the bud.")

An example of an issue which the group has sorted out in recent months is the rising incidence of "retrolental fibroplasia" (RLF) among the premature infants.

RLF, explains Sunshine, is a condition in which the underdeveloped vessels of the retina in certain premature infants grow in an aberrant way. If not surgically treated, it can eventually lead to blindness.

"There were a lot of bad feelings and even some guilt at the larger number of infants with RLF," says Palange. "But when we talked about it, we were able to determine that the problem was an unfortunate but currently unavoidable byproduct of saving increasingly smaller and smaller babies." (Sunshine says an alleviating ingredient has been greater awareness of the situation through involvement by members of the Division of Ophthalmology).

"This was an excellent example of nurses and doctors putting our heads together and discussing a problem facing us all, while at the same time relieving tensions caused by a lack of knowledge," Palange says.

Adds Sunshine, "We also realized we'd be seeing more of this particular disorder and became more alert in looking out for it."

Though attendance at the meetings is optional, says Sunshine, "the room is always packed." At least 20 persons attend each time. This includes personnel other than nurses and physicians, such as respiratory therapists, who are also invited to attend.

AUSTERITY BUDGET APPROVED FOR MEDICAL SCHOOL

STANFORD—

Stanford University School of Medicine will have a balanced operating budget in fiscal 1982-83, but austerity measures were necessary to achieve it.

Approved Tuesday by the University Board of Trustees, the School's $26.6 million budget will be 8.5 percent higher than the current year's $24.5 million. The operating budget, which excludes sponsored research and Faculty Practice Plan, covers faculty and staff salaries and benefits, academic support services, administration, maintenance, utilities, and the Lane Medical Library.

According to Dr. Lawrence G. Crowley, vice president for medical affairs and acting dean, a long-range forecast had predicted that two of the largest expense categories—salaries and staff benefits, and utilities—have been growing much faster than income.

Consequently, Crowley explained, the budget strategy for the coming year was to fund at the necessary levels those functions controlled centrally—utilities, operations and maintenance, and academic support—while reducing the growth rate in administration and obliging academic departments to increase their reliance on departmental gifts and other discretionary funds.

Crowley said very limited growth in faculty size is anticipated in the new budget. Faculty and staff salary increases will follow the general University guidelines, and internal inequities and market comparisons will be addressed as needed.

(Under the general guidelines faculty salaries would increase 10.5 percent, with raises above that level in special cases. A general range adjustment of 10 percent plus step or merit zone increases is proposed for nonexempt employees.)

Energy costs, a large budget item, are predicted to increase 16.8 percent. Utility bills comprise 13 percent of the Medical School's operating budget for the coming year.

Sources of income for the School's operating budget include indirect costs on sponsored research (40 percent); tuition income (19 percent); and income from the Faculty Practice Program (7.4 percent). The balance of income is provided by unrestricted gifts, earnings on reserves, and the payout from endowment.

"Attention in developing the new budget," Crowley said, "has been focused on the total financial needs of the School over the next several years.

-more-

"These needs include not only monies to fund the operating budget, but also funds to increase the operating reserve and funds for capital projects."

Noting that already several major capital projects have been planned and approved by the trustees, Crowley said the reserve must be maintained and replenished so that future projects can be funded.

About $2 million or more per year, based on the present value of the School's capital facilities, will have to be put in reserve each year, Crowley said.

"Because of the current financial climate, the amount budgeted for capital needs reaches about half that goal," he added. "But we believe it is a significant step in the development of a responsible capital plan."

Crowley said the School is also establishing "a research facilitation fund" beginning with the 1982-83 budget. This is in anticipation of potential shifts in federal research policy and funding levels.

"The fund is designed to provide interim one-time funding to researchers who have had their grants reduced and who have no other resources available to assume the short fall," he said.

Crowley pointed out that although the faculty has done well in past periods of tight federal funding, nearly all of the Medical School's income sources are highly vulnerable to changes in government fiscal policies.

"Medicare affects the Faculty Practice Plan's income," he said. "Research support affects indirect cost recovery, and interest rate fluctuations affect earnings on the School's reserves and endowment while tax laws affect gift income.

"We, therefore, must continue to monitor income and expense to remain viable as an institution during the difficult times ahead."

STANFORD—

Sheldon King, the new director of Stanford University Hospital, is clearly at home in the academic world which surrounds his hospital environment.

"I've been involved in health care policy formation at the state and federal levels, but that has been an interest secondary to hospital management," he says.

"I believe I do understand what it takes to make a large teaching hospital run effectively. That's what I'm here for, and essentially it is what I'm interested in professionally.

"But I keep in mind the unique characteristics of a teaching institution and have always felt that teaching actively helps me to understand the academic interest better. Working with students is something I enjoy."

King, 50, has spent all his working life in teaching hospitals, starting as a $35 a month administrative intern at Montefiore Hospital in his native New York City.

"I've worked only in teaching hospitals, and over time I understood that this is where most of the progress in American medicine takes place. I want to continue to be part of that field."

His current focus is a 663-bed hospital which must delicately balance the research and teaching needs of a university with the patient care needs of an urban community.

King's job, among other things, is to help keep that balance.

The first scene, that first teaching hospital assignment at Montefiore, was interrupted after a few months in 1953 when King was drafted.

"But I had discovered that I enjoyed that kind of work and so I applied to the Yale University graduate program while I was in the Army."

Back in the hospital world, King served in several slots, including director of planning at The Mount Sinai Hospital in New York, then moved to Albert Einstein College of Medicine—Bronx Municipal Hospital Center as executive director from 1968 to 1972.

Then he moved West. Until he came to SUH last November, King served for almost 10 years as director of hospital and clinics at University Hospital, University of California Medical Center in San Diego.

"At the risk of sounding immodest, my main accomplishment was assembling and leading an administration which worked with the faculty to turn that facility from a county hospital into a signficant teaching hospital."

Then it was time to move on.

"I think that when someone has been a major teaching hospital director at any institution for a significant period, it's time to take a very careful look and decide whether there is any point in continuing there.

"i think you can run out of fresh ideas which can be applied to the same place. You tend to become less creative if you stay in one place if the major challenges have faded.

" . . . The way I felt was that after the number of years I had worked in the governmental sector, I was looking for a system which was flexible and freer to direct its own future. I believe that is what Stanford represents and does.

"The involvement of the president of the University in this medical center was a signficantly positive point.

" . . . Frankly, Stanford was one of the few places I felt I could live and work, and when the opportunity presented itself, I took advantage of it."

Leaning back in his chair, King reflects on a lot of specific issues. Since he's only been on the job since last Nov. 9, he admits a bit of conflict between a need to study and learn his new arena and a desire to move ahead. He constantly reminds himself that his job indeed is to *run* an efficient, effective hospital.

-more-

Yet, King concedes that he cannot divorce himself from larger issues, like serving on a reasonable number of national health advisory committees (including the Council of Teaching Hospitals).

He has written papers and articles on techniques of management. He is a proponent of what he calls the management planning program, a system of leadership in which annual goals are developed by the director and the staff and then negotiated as specific objectives to be accomplished by individual staff members.

The goals are listed on checkoff sheets, providing a clearcut record of expectations and a method for administrators to judge the accomplishments of subordinates through benchmarks and measurable results.

King quickly acknowledges that he is too new to have completely firmed up all specific policy directions for his new hospital.

But he emphasizes that his general views on how teaching hospitals should be run are firmly in place on such issues as the role of the institution in the community, the relationship of a hospital with doctors, and the issue of providing balanced health care programs.

On the latter, King firmly believes that Stanford can combine its role as a tertiary, or highly specialized facility, with its role as a community hospital.

"I think we can do both . . . that with 650 beds we're large enough."

The Hospital Modernization Project (HMP) will enable SUH to combine both roles more effectively, King believes, and he points as an example to the expansion of the operating rooms from 16 to 24 as part of the sweeping improvement project.

Key to providing a balance of community and research services is a harmonious relationship between the full-time faculty and local physicians in private practice who treat their patients at Stanford.

"There's a board committee looking at access now, and I think that is going to be an extraordinarily important committee.

"I think that access is an essential issue for our community physicians."

But another issue, said King, is to increase patient amenities to ensure that Stanford will continue to be a hospital of choice for the community.

"Now I'm not necessarily talking about providing lobster and filet mignon at every meal, but I am talking about providing an improved environment. Some improvements can be made at little or no cost.

"Of course until the HMP is completed, the Hospital is limited physically. It doesn't take more than a glance to tell you that the rooms are too small—patient care rooms are just too small.

"How much can we do about that? I don't know yet. But certainly there are some basic things which could make a lot of difference.

"The plant needs a general freshening. I think it needs a general spruce-up. I think a number of the service areas need work—that's where an emphasis should be placed. Much of our task is not just changing things physically, it's the way people relate to patients.

"And certain other changes might not even require any money. For example, I think there is a failure to understand the Hospital bill. Now to produce a bill that the patient can understand doesn't cost any more than one they can't understand. Is that a patient amenity? I think it is."

A sensitive issue for King is balance among clinical programs:

"What I pushed for in San Diego was a hospital that was generally excellent. Maybe it really had no superstars. There were several things (including a neonatal intensive care unit) which they did extraordinarily well. Perhaps not as well as Stanford does the things it does extraordinarily well. But as a hospital it was solid at every level.

"I'm not sure that we are quite as well balanced at this point, meaning that quite frankly, some of our programs are outstanding, while others aren't."

" . . . One wants to preserve the excellence that already exists. But it has to be done in an environment that gives other programs a chance to develop, too. So the answer is probably that there will be compromises that haven't existed before and inevitably some reshifting in priorities.

"It comes back to being able to develop a medical center that fulfills one of its main purposes, which is the education of health care professionals. You do not educate medical students and housestaff well in anything other than an environment which is well balanced, one where patient care is our primary concern."

-more-

3-3-3 King believes that his role as a nonmedical person is crucial in bringing balance, partly because doctors may have a blind spot when it comes to management and tend to focus exclusively on their specialties.

"And that's also one of the reasons departments become singularly successful, but it's also why you need a general manager—to make sure the priorities and the allocations are reached in a reasonable way."

Specifically, King would seek to attract new kinds of patients, including the elderly who are making up an increasingly larger proportion of both the nation's and the Peninsula's population. And in a second category, "I think we're going to have to relate to HMO (health maintenance organizations, prepaid plans) populations in different ways than we do now.

"I don't know what all the conditions are, but it's clear that in a competitive market with the continued emphasis on prepayment plans and on buying the least expensive comprehensive plan possible, we're going to have to get into that business either cooperatively or independently—and that's an issue both for the faculty and for the Hospital.

King also cited Stanford faculty and staff as potential patients.

"We ought to be able to make this place so attractive to them for care that they don't go anywhere else. I don't know that we do that yet.

". . . Again, it's really an issue of balance and an agreement on goals and directions. After these are determined, we must proceed towards our objectives in an integrated and measurable way. That's simple to say, but I've not experienced it to be simple to do.

"That's the challenge, and I wouldn't have come here without challenges. It's stimulating to come to a hospital that's not in crisis, where the opportunities lie before us."

And on his leadership role there appears room for subtlety but not ambiguity.

For example, King's office is decorated with professional quality photos he has taken of his Indian pottery collection. ("I never thought of the collection as a hobby, and I certainly didn't think of the photos I took for insurance purposes as a hobby. But I guess they are.")

His office wall also includes a painting of a tiger with flattened ears.

"The position of those ears is important," King explains. "That means he's alert, he's ready and tough. I do feel that represents my own attitude, at least at times. I have a habit of pointing out the signficance of that painting to friends on the faculty only when necessary."

King says he believes in participation in management by as many of the staff as possible and feels that department heads—not top administrators—are the key management group in the Hospital.

"I don't know whether we tap them for the advice that we ought to. There's a tendency for hospital directors to try to make decisions at some lofty level. I think that's an error.

". . . (But) I am also not a democrat. I believe there is a participatory process—but without voting. And if I decide after listening to everyone that I should do what two-thirds think is not going to be done, we're going to try it anyway. Because that's what I'm here for.

"I believe in delegating as much as I can to anyone who will take on authority and is capable of making decisions intelligently, responsibly and in the context of what the overall plan is. But I intend to be part of the process."

For the future, King believes that perhaps too many levels of management exist and that some long-term restructuring might be desirable. But he adds that no precipitous changes are in the offing.

"I would hope to try to establish an environment in which people are less suspicious of each other and perhaps prepared to work together."

King's move to Stanford involved some personal sacrifice, since his family will not be able to join him until next summer, when his daughter will finish high school and his wife will have fulfilled her work obligations. King's wife, Arden, is administrator of the San Diego Psychoanalytic Institute, "and has gotten to the stage in her career where she's ready to change jobs, too."

The Kings' older daughter, Tracy, is 20 and a junior at Princeton, majoring in American literature and American studies. The 17-year-old daughter, Meredith, is a senior at La Jolla High School, a promising volleyball player who had considered seriously applying to Stanford before her dad decided to move north. A son, Adam, 14, "is looking forward to coming here. He's the only one of the children who will be affected by the move in terms of where he goes to school."

MEDICAL SCHOOL COMMITTEE WANTS TOUGHER CONSULTING RULES

STANFORD -

A special committee of the Stanford University School of Medicine has recommended that faculty members be required to disclose their private consulting ties.

The committee wants tougher rules not only because outside faculty activities have the potential of distorting the Medical School's educational objectives, but also because the faculty plays a unique role in the development and application of new diagnostic tools and therapies ultimately tested and used on patients.

"Certain abuses of consulting privileges," explained committee chairman Eric Shooter, "could diminish public trust in biomedical research, in its practitioners and applications."

Shooter, professor and chairman of the Department of Neurobiology, headed the eight-member faculty committee which formulated the newest recommendations. They will be debated by the faculty and the School's executive committee before they are approved by the dean of the Medical School and the vice president for medical affairs.

The committee was appointed a year ago by Dr. Lawrence G. Crowley, vice president for medical affairs, to examine the rules that should govern nonclinical consulting activities of the full-time medical faculty in light of Stanford's consulting policy.

Under Stanford's policy, faculty members with full-time 12-month academic appointments may consult one day per week or 52 days per year. Potential conflicts of interest must be disclosed "upon request" from the relevant dean, the provost or the president.

The Shooter committee agreed with the University policy and its definition of consulting, but determined that disclosure "upon request" may not be sufficient to cover possible conflicts of interest in the Medical School.

The faculty "should report their consulting activities to the department chairperson on a continuing and formal basis," the committee suggested.

Disclosure reports could be made on a simple standard form that would elicit information concerning the nature and scope of the faculty member's nonclinical consulting activities.

- more-

"These reports," the committee added, "would be reviewed by department chairpersons who may request additional information. A faculty member would be expected to answer relevant inquiries regarding financial arrangements and commitment of time to . . . consulting activities."

Department chairmen would submit reports about their own consulting to the dean.

The committee expressed concern about potential conflicts that may arise during clinical trials in which faculty members test new procedures, drugs, or equipment.

"There is a reasonable likelihood that materials being studied in the trials will be supplied by commercial entities with which they (faculty) consult or in which they have substantial financial interest, or by companies that are competitors of the companies with which they consult.

"To blunt or eliminate the perception of conflict of interest, but not to deny the opportunity to conduct such trials to faculty members, we recommend that the Human Subjects Experimentation Committee devise a procedure which discloses the relevant consulting or financial interests of the faculty member . . . during the review of experimental protocols."

The committee listed examples of practices that it believes present potential conflict of interest or commitment. These include:

- instances in which a faculty member directs students into research devised principally to serve his or her interests and from which there may be financial gain.
- Placing the financial interests of an outside firm ahead of those of the University.
- Transferring the fruits of University research without approval to a commercial enterprise from which a faculty member receives consulting fees.

"Less blatant, but no less serious to the intellectual aims of the School are activities which create conflicts of commitment, that is situations in which . . . creative energy that faculty members devote to consulting compromises their commitment to University responsibilities," the committee said.

Conflicts of commitment, the committee added, can arise not only from industrial consulting, "but also from excessive teaching or collaboration at other institutions, commercially-run postgraduate courses, participation in nonscholarly writing, movies or moonlighting."

In addition, the committee addressed an issue which is unique to the Medical School. While all medical faculty members may engage in nonclinical consulting, the prevalent form of consulting for clinical faculty is when they are requested to assist a colleague on a case, provide a second opinion and so on. Under present rules, faculty clinicians must turn over their consulting fees to the Faculty Practice Program.

This requirement was imposed because of the need to protect the availability of teaching patients and the clinical income which supports in part the clinical departments and the operating budget of the School.

The committee said "now is an opportune time for an appropriate faculty group to determine if the two forms of consulting income are appropriate."

The School, it suggested, might consider "devising a mechanism, perhaps, but not necessarily analogous to the Faculty Practice Plan, for sharing nonclinical consulting income for the general purposes of the School."

The committee members included Paul Berg, professor of biochemistry; Stanley Cohen, professor and chairman of the Department of Genetics; John A. Collins, professor and chairman, Department of Surgery; Hugh O. McDevitt, professor of medical microbiology and medicine; Kenneth Melmon, professor and chairman, Department of Medicine; William H. Northway, Jr., professor of radiology; and John L. Wilson, professor of surgery and associate dean for faculty affairs.

NEW BANK MAKES LANGUAGE LOANS

STANFORD—

For Stanford patients who don't speak English, the Hospital environment can be extra frightening and relaxation nearly impossible.

It is for this reason that the Department of Community Relations has developed a "translator bank" of community members willing to volunteer linguistic assistance to patients when such need arises.

Although four professional Spanish interpreters, one deaf interpreter, and many bi- and multi-lingual Hospital employees regularly provide translation services, they cannot handle all the assistance needed in languages from all over the world, explains Jeanne Kennedy, director of Community Relations.

"And we never know how much help we'll need in a specific language. Any day someone might come in who speaks a language we've never dealt with."

Through the efforts of Kennedy's office, the Hospital now has a reserve of 52 volunteers representing 23 different languages to draw upon.

The number of times each volunteer will be asked to help is probably small, Kennedy says, perhaps only once a year. But the effect on the patient's welfare will be enormous, she predicts.

While the group may well increase in the future, the languages so far included in the bank are: Armenian, Brazilian Portuguese, Chinese, Dutch, Finnish, French, German, Greek, Indonesian, Italian, Japanese, Persian, Philippino, Polish, Russian, Serbo-Croatian, American Sign Language, Spanish, Swedish, Taiwanese, Turkish, Ukrainian, and Yiddish.

Volunteers vary in their degree of fluency, which is part of the information listed in the Translator Directory recently distributed in the Medical Center. Also included in the directory are the participants' available hours and phone numbers.

The Office of Community Relations, says Kennedy, is to serve as home base for the program, as well as the place to go when questions or problems occur.

An orientation program was held recently for the volunteer translators, to offer an idea of what kinds of situations may be encountered as well as possible ways to deal with them.

During the orientation, one volunteer shared a previous translating experience she'd had when the mother of a Finnish teenager who was about to undergo a heart transplant at Stanford couldn't have been more grateful for the supportive assistance she provided.

Many of the new volunteers, says Kennedy, are not new to translation, having participated in such programs at other hospitals. Several of Stanford's Auxiliary members have joined the group, which includes people from all walks of life.

Those with specific questions about the new translator bank should call Community Relations, at 497-7167, and ask for Marty Kortebein.

HOME PROJECT GIVEN BOOST

STANFORD—

The Lowell Berry Foundation of Oakland has given $4000 to the Assistance League of Santa Clara County to be used by its committee on Housing of Medical Emergencies, HOME.

For about four years, HOME has provided subsidized housing at the Oak Creek apartments for a few Stanford outpatients and their families, according to financial and medical need.

Each of four furnished apartment units houses two people: the patient and a relative. The charge is much less than that of nearby motels or rental housing. Among the long-term patients who have benefited under the program are heart transplant recipients and people with cancer.

To support its activities, the Assistance League runs an on-going fund raising program in the form of a costume rental shop at its chapter house in Los Altos.

The Lowell Berry Foundation, established in 1951, generally supports religious, Christian-oriented programs, as well as some civic organizations. Berry was a 1924 Stanford graduate who demonstrated generosity towards the University throughout his lifetime. Among other gifts was the establishment of an endowment fund in the name of one of his daughters, Jayne Annette Berry.

Current directors of the Foundation chose to help HOME when they read an article about the program in Stanford's *Campus Report* last fall. Their gift arrived with no stipulations at the end of February, and has already been put to use refurbishing two of the apartments.

COURSE EXPLORES MORAL DILEMMAS OF CRITICAL CARE

STANFORD—

In a classroom on the Stanford campus crammed with undergraduates, the young doctor takes the podium as the pre-class hubbub falls away. He begins: "In the last 11 days in the intensive care units of Stanford Hospital we helped four people die. As health professionals, we do not only fight death. We accept death when it is inevitable."

Clearly, this course is not the usual classroom fare.

The day's topic is death and dying; the course, offered through the program on human biology, is called "Intensive life support systems: present practice and moral issues." The syllabus is packed with highly emotional and controversial topics to make the squeamish cringe: coma, intensive care unit psychosis, the dying patient, withdrawing life support from the critically ill patient, cost-effectiveness of intensive care units.

But the students who signed up for the course are far from squeamish. Many of them are "pre-med," intent on entering medical school. They are hungry for knowledge about current medical practice.

The course was organized by Dr. Thomas Raffin, assistant professor and assistant chief of medicine and associate director of the Hospital's intensive care units, and Charles Weitz, a 4th-year medical student.

It is organized into three components: the biomedical technology that makes intensive care possible; the psychological, social, legal and ethical issues surrounding death and dying; and the costs of intensive care medicine.

"Through this course, we hoped to focus on the moral issues surrounding which patients should be admitted to intensive care units, how to help those who can live, and how to help those who are dying to have a good death," Raffin explains.

Biotechnology has spawned marvelous equipment and life support systems that can prolong life: the challenge is to know when and how to use this technology in the best interest of each patient and society as a whole, Raffin adds.

"We knew undergraduates are very excited at the idea of learning about intensive care units and grappling with the issues that arise—but they just haven't had access to this information," Weitz explains. Judging from the enrollment, the course does seem to have struck a chord—over 100 students are taking the elective.

But if the fuel for the course is intensive care medicine, the burning issues involve death.

"Today, up to 80 percent of people die in institutions, whereas in the early 1900s only 10 or 20 percent died outside their homes," Raffin points out. "Coping with death has now become a routine part of intensive care medicine."

Raffin emphasizes that the key to humane practice of ICU medicine is in the approach to death. "If death is inevitable, dignity is essential," he stresses. "Is it dignified to die naked under a sheet with 14 tubes coming out of your body? If you withdraw support, let the patient die with dignity. If the patient has a month left to live, and is able to go home, let him."

-more-

A large problem in ICUs is the "distancing" that goes on, both on the part of patients and family, and by physicians and other medical personnel, Raffin says.

The words 'death' and 'dying' need to be used if they are applicable, according to Raffin. "Some physicians use elaborate euphemisms to avoid this," Raffin observes, "such as 'your wife is as sick as any human can be'.

"These doctors don't have bad intentions—it's just that they know the word 'death' can trigger an outpouring of emotion, and many physicians find the stress of dealing with this emotion on a daily basis too much to bear. It's a self-protective device."

Raffin told the class an anecdote about a five-year old boy with leukemia whose parents couldn't face telling the boy that he was dying. One night his nurse came in and the child asked her to sit by him holding his hand. Then, according to Raffin, he told the nurse that he thought he was dying. That evening he was dead.

"If you can't fool a five-year old child, you certainly aren't fooling an adult when you deny impending death," Raffin remarks.

"It's important that everyone get an understanding of intensive care units," Raffin contends. "Their relatives, friends and they themselves stand a good chance of being treated in an intensive care unit or of dying in one."

How closely ICUs have touched many was revealed early in the course, Raffin recalls. On the first day of class, he requested a show of hands to determine how many students had seen an intensive care unit. "About half had visited one, and two students had actually been intensive care patients themselves," Weitz adds.

But in addition to providing a personal understanding of ICUs and hospital care, the course is important for another reason, Raffin says. "These students (in the human biology program) have a broad social science background. In the future, they may be able to lend insight on problems of intensive care and are likely to be involved in policy decisions that affect medical practice."

One of the requirements for passing the course is a visit to the ICU at Stanford University Hospital, Raffin says.

Small groups of students meet with several intensive care nurses who show them the ins and outs of routine ICU care and life support procedures.

The nurses also demonstrate and explain ICU equipment: ventilator, intra-aortic balloon pump, chest tubes, cooling blanket, dialysis machine, emergency trays. And they discuss with the students the painful process of withdrawing life support, in which the entire medical care team and the family must participate.

The students must also prepare term papers dealing with intensive care, says Weitz. "They range from nurse burnout in ICUs to the biomedical science behind transplantation."

Raffin and Weitz feel gratified at the impact of the class. Despite its large size, people don't hesitate to speak up frequently with questions and in discussions.

DIAGNOSTIC TESTS FOUND TO HAVE PLACEBO EFFECT

STANFORD—

If a doctor orders certain types of diagnostic tests it can speed a patient's recovery even if the tests provide no useful medical information, according to a recent Stanford University School of Medicine study.

The mere fact that the tests have been performed seems to have a positive psychological effect that translates into more rapid return to full activity in patients with minor chest pain, said Dr. Harold Sox, associate professor of clinical medicine and head of the division of general internal medicine at Stanford.

"This is the first study to systematically examine the psychological effects of diagnostic tests on patient outcome," Sox said. "The study ties together previous information documenting that placebo drugs (medications with no objective treatment value) can reduce disability and pain, with physicians' intuition that administering laboratory tests may help patients recover more quickly.

"Just as with prescribing placebos, many doctors believe that certain patients will benefit from having tests that are almost certain to be normal. Our study provides for the first time a scientific basis for this belief," Sox added.

The study was carried out on 176 patients complaining of chest pain in whom heart disease was ruled out as the cause. This was done by applying previously validated rules to analyze the medical information obtained from a carefully formulated set of questions asked during the patient's physical examination.

The selected patients were told that there was very little chance of their pain being caused by heart disease, and then they were placed in two groups for follow-up. One group received no further diagnostic testing, while patients in the other group underwent blood-enzyme tests for heart disease and a 12-lead electrocardiogram (ECG), even though a cardiac basis for their pain had already been eliminated.

At a follow-up examination three weeks later, about four-fifths of the patients who had received the diagnostic tests were fully active while about half of those patients who had not received the ECG and blood test were inactive and still complained of disability. (At a four-month follow-up, the percentage of patients still debilitated by their pain equalized in both the test and no-test groups.)

"Our results show that diagnostic tests have side effects which measurably influence patients," Sox noted. "We suspect that reassurance plays a role in hastening recovery in those patients who undergo the diagnostic tests, but we have no direct evidence for this as yet."

-more-

Results of the study, carried out by Sox and two associates, Iris Margulies and Carol Hill Sox, were published recently in the *Annals of Internal Medicine*. The research was funded by grants from the Veterans Administration.

Sox cautioned that the results from this study should not be applied indiscriminately.

"So far, we have only looked at patients with chest pain and the use of ECG and serum creatine phosphokinase (blood test). That does not mean doctors should, for example, automatically order x-rays of the back for every patient with back trouble. You have to balance the cost and risks of the tests with the possible psychological benefits to the patient, as documented in reliable scientific studies," he said.

Sox acknowledged that, at first glance, results from his study may seem to run counter to the move towards cost containment in medical care: ordering laboratory tests with minimal diagnostic value does not seem cost-conservative.

However, the goal of cost containment is to reduce as far as possible the overall cost of illness to society. This includes indirect costs of disability such as lost time from work and frequent patient visits to the physician. Since these are minimized when patients recover quickly, he noted, tests done solely for psychological benefit may be justifiable for some patients.

Not every patient benefits from the psychological boost of a diagnostic procedure, Sox added. "For instance, in our study, patients who were under 50 years old, those who said they could 'do anything' in the month before coming to the doctor and those who felt very healthy except for the chest pain, gained no psychological edge from additional diagnostic testing," Sox observed.

He also pointed out that occasionally even highly reliable laboratory tests give "false positive" results, indicating presence of illness where there is none. This can lead to worry and even further unnecessary testing, Sox said.

False positive results, which can occur in as many as 10 percent of normal persons with many diagnostic tests, underscore the need to be sure of reasonable benefit before ordering tests just for their psychological effect, Sox said.

In future studies, Sox and his colleagues plan to test methods for predicting which patients are most likely to reap psychological benefit from diagnostic testing. They also intend to compare recovery rates in patients who receive diagnostic tests with those who simply receive words of reassurance in the examining room by the physician or other health care provider.

FOR INFORMATION CONTACT: Mike Goodkind (415) 497-6911

(Editors: The following story was released via telecopied transmission and regional wire service distribution on Sunday, March 7)

STANFORD—

Registered nurses at Stanford University Hospital have overwhelmingly ratified a two-year collective bargaining agreement, the hospital and the union representing the nurses announced Sunday.

In a joint statement, Priscilla Wheeler, Stanford's chief labor attorney; and Hedy Dumpel, president of the Committee for Recognition of Nursing Achievement (CRONA) said:

"We are pleased that through the process of bargaining in good faith, we are able to mutually develop an agreement which meets the needs of the hospital and the nurses.

"The new contract provides for increased wages for the nurses while recognizing the hospital's responsibility to continue to provide the highest quality health care at the fairest possible cost."

Wheeler and Dumpel headed the respective negotiating teams which had been talking regularly since Jan. 13.

One feature of the pact is the establishment of a Committee on Nursing Practice to discuss issues relating to the profession, including standards.

"It's important to recognize that nursing is a profession with high standards to uphold, Dumpel said.

The approximately 1,250 nurses represented by CRONA accepted the new contract by a more than 10 to 1 margin. The tally disclosed that 912 of 992 nurses voting in all-day elections Saturday favored the new contract, which will give nurses at the highest skill level with more than 5-and-a-half years experience a base salary of $31,283 the first year, rising to a maximum of $35,298 in the second year.

Starting nurses will receive a minimum of $21,985, while the night differential has been increased from 14 to 16 percent of base pay.

Both the old and new contracts had provided four skill levels. The old contract had six steps within each level, while the new agreement adds a seventh step for nurses with 5-and-a-half or more years of service.

In general, the new contract provides at least a 10 percent increase the first year, with an 8 percent rise in the second year. The negotiators said adjustments to length of service steps on the pay scale will further increase most nurses' base wages from 1 to 4 percent depending on step placement. Nurses in the new seventh step will receive the highest increase.

In their last 20-month contract, ratified July 8, 1980, nurses received three wage increases of 12, 3 and 9 percent.

Tentative agreement was reached last Thursday, four days after a 20-month contract had expired. At the same time, a 10-day strike notice issued Feb. 26 was rescinded.

The hospital cancelled a small number of scheduled non-emergency admissions after a 10-day strike notice was isssued Feb. 26, but operations at the 663-bed hospital were returned to normal immediately after tentative agreement was reached and the strike notice rescinded.

The hospital negotiating team included Wheeler, Dan Robinson, assistant director of personnel; Nancy Madsen, assistant hospital director and associate director of nursing; and two assistant directors of nursing, Joyce Miller and Eileen O'Reardon.

Representing CRONA were Dumpel; and five registered nurses, Patti tharp, Alice Serbein, Sue Healy, Linda Stickles and Jan MacLachlan.

STANFORD-REGISTERED NURSES AT STANFORD UNIVERSITY HOSPITAL HAVE OVERWHELMINGLY RATIFIED A TWO-YEAR COLLECTIVE BARGAINING AGREEMENT; THE HOSPITAL AND THE UNION REPRESENTING THE NURSES ANNOUNCED SUNDAY.

IN A JOINT STATEMENT; PRISCILLA WHEELER; STANFORD'S CHIEF LABOR ATTORNEY; AND HEDY DUMPEL; PRESIDENT OF THE COMMITTEE FOR RECOGNITION OF NURSING ACHIEVEMENT (CRONA) SAID:

''WE ARE PLEASED THAT THROUGH THE PROCESS OF BARGAINING IN GOOD FAITH; WE ARE ABLE TO MUTUALLY DEVELOP AN AGREEMENT WHICH MEETS THE NEEDS OF THE HOSPITAL AND THE NURSES.

''THE NEW CONTRACT PROVIDES FOR INCREASED WAGES FOR THE NURSES WHILE RECOGNIZING THE HOSPITAL'S RESPONSIBILITY TO CONTINUE TO PROVIDE THE HIGHEST QUALITY HEALTH CARE AT THE FAIREST POSSIBLE COST.''

WHEELER AND DUMPEL HEADED THE RESPECTIVE NEGOTIATING TEAMS WHICH HAD BEEN TALKING REGULARLY SINCE JAN. 13.

ONE FEATURE OF THE PACT IS THE ESTABLISHMENT OF A COMMITTEE ON NURSING PRACTICE TO DISCUSS ISSUES RELATING TO THE PROFESSION; INCLUDING STANDARDS.

''IT'S IMPORTANT TO RECOGNIZE THAT NURSING IS A PROFESSION WITH HIGH STANDARDS TO UPHOLD; DUMPEL SAID.

THE APPROXIMATELY 1;250 NURSES REPRESENTED BY CRONA ACCEPTED THE NEW CONTRACT BY A MORE THAN 10 TO 1 MARGIN. THE TALLY DISCLOSED THAT 912 OF 992 NURSES VOTING IN ALL-DAY ELECTIONS SATURDAY FAVORED THE NEW CONTRACT; WHICH WILL GIVE NURSES AT THE HIGHEST SKILL LEVEL WITH MORE THAN 5-AND-A-HALF YEARS EXPERIENCE A BASE SALARY OF $31;283 THE FIRST YEAR; RISING TO A MAXIMUM OF $35;298 IN THE SECOND YEAR.

--MORE--

STARTING NURSES WILL RECEIVE A MINIMUM OF $21,985, WHILE THE NIGHT DIFFERENTIAL HAS BEEN INCREASED FROM 14 TO 16 PERCENT OF BASE PAY.

BOTH THE OLD AND NEW CONTRACTS HAD PROVIDED FOUR SKILL LEVELS. THE OLD CONTRACT HAD SIX STEPS WITHIN EACH LEVEL, WHILE THE NEW AGREEMENT ADDS A SEVENTH STEP FOR NURSES WITH 5-AND-A-HALF OR MORE YEARS OF SERVICE.

IN GENERAL, THE NEW CONTRACT PROVIDES AT LEAST A 10 PERCENT INCREASE THE FIRST YEAR, WITH AN 8 PERCENT RISE IN THE SECOND YEAR. THE NEGOTIATORS SAID ADJUSTMENTS TO LENGTH OF SERVICE STEPS ON THE PAY SCALE WILL FURTHER INCREASE MOST NURSES' BASE WAGES FROM 1 TO 4 PERCENT DEPENDING ON STEP PLACEMENT. NURSES IN THE NEW SEVENTH STEP WILL RECEIVE THE HIGHEST INCREASE.

IN THEIR LAST 20-MONTH CONTRACT, RATIFIED JULY 8, 1980, NURSES RECEIVED THREE WAGE INCREASES OF 12, 3 AND 9 PERCENT.

TENTATIVE AGREEMENT WAS REACHED LAST THURSDAY, FOUR DAYS AFTER A 20-MONTH CONTRACT HAD EXPIRED. AT THE SAME TIME, A 10-DAY STRIKE NOTICE ISSUED FEB. 26 WAS RESCINDED.

THE HOSPITAL CANCELLED A SMALL NUMBER OF SCHEDULED NON-EMERGENCY ADMISSIONS AFTER A 10-DAY STRIKE NOTICE WAS ISSSUED FEB. 26, BUT OPERATIONS AT THE 663-BED HOSPITAL WERE RETURNED TO NORMAL IMMEDIATELY AFTER TENTATIVE AGREEMENT WAS REACHED AND THE STRIKE NOTICE RESCINDED.

THE HOSPITAL NEGOTIATING TEAM INCLUDED WHEELER, DAN ROBINSON, ASSISTANT DIRECTOR OF PERSONNEL; NANCY MADSEN, ASSISTANT HOSPITAL DIRECTOR AND ASSOCIATE DIRECTOR OF NURSING; AND TWO ASSISTANT DIRECTORS OF NURSING, JOYCE MILLER AND EILEEN O'REARDON.

REPRESENTING CRONA WERE DUMPEL; AND FIVE REGISTERED NURSES, PATTI THARP, ALICE SERBEIN, SUE HEALY, LINDA STICKLES AND JAN MACLACHLAN.

EVERYTHING YOU WANTED TO KNOW ABOUT STANFORD MEDICAL CENTER OFFERED IN NEW TOUR

STANFORD—

It may not be in the Michelin guide, but Stanford University Medical Center nevertheless draws an international crowd of tourists.

Of course, the Eiffel Tower and Disneyland probably pop into your mind first when you think of tourist attractions, but you might be surprised to know that a regular flow of wide-eyed visitors also streams through Stanford Medical Center.

Over 1,000 visitors in the last nine months have been guided through the research and patient care labyrinth that makes up the sprawling medical complex, as part of a new and upgraded tours program based in the Medical Center's Office of Public Events, which is headed by Michael Cowan.

Like tourists anywhere, they come in all shapes and sizes, says Linda Northway, who put together and coordinates the new tour package. One day, a group of eager and career-curious high school students from San Jose will file through; the next day, it might be a dozen camera-laden surgeons from Japan.

Conducting the tours is "fascinating and fun," confesses Northway. "We meet people from all over the world."

"What we try to stress to all of our groups is the uniqueness of a university medical center, and the way in which patient care, teaching and medical research coalesce," Northway explains.

Among the stops along the tour route are two intensive care units—one for infants and one for adults—the emergency department, the operating room suite, one of the science research buildings, the clinics, and the teaching wing of the Medical School.

This spring, the tour program is swinging into high gear, with the help of five docents who just completed Northway's rigorous training course: four volunteers from the Medical Center Auxiliary—Linda Gill, Dorothy Mintz, Joan Naber, and Del Winslow—and public events assistant Marty Vetter. In addition to leading the regularly scheduled hour-long Thursday tour that begins at 1:30 p.m., Northway and her newly trained guides conduct special tours for groups on a request basis.

-more-

If there are special interests, tours can be modified to include special stops or speakers who can elaborate on a specific subject. "Staff and faculty have been wonderfully helpful," Northway says, "particularly in the time they put aside to help young people who are interested in health care careers."

The new tours have been popular not only with out-of-towners and young people—there is growing demand for the tour from people in the community and, particularly gratifying to Northway, from those who work in the medical center and want to find out more about the institution.

The tour provides an illuminating glimpse of a modern medical center, highlighting new treatments and advanced basic research. "We try to convey the excitement and sense of purpose in this busy medical center," she says, "without overwhelming people."

Northway spent several months collecting information from a cross-section of faculty and staff in the medical center, distilling the reams of knowledge into a handbook of source material for her tour guides' training. For four months, the tour guides-to-be then studied the handbook for three hours each week and visited areas in the center to learn first-hand about its myriad activities.

"We have all ended up with extensive background that enables us to answer many questions in depth," says Northway, who is no novice at tour activities. (She spent ten years as a docent with the Stanford Museum and several more in charge of tours through Frank Lloyd Wright's Hanna-Honeycomb house on the Stanford campus.) "We wanted to match the high professional caliber of Stanford Medical Center with an equally professional tour program."

For information about routine tours or to schedule a special one for a group, call Northway at 497-6389. The tour program will be recruiting additional guides as time goes on. Anyone interested in further information about training to become a guide can also give Northway a call.

NEW WAY TO DIET RELIES ON THE POST OFFICE

STANFORD—

Losing weight by mail may sound like someone's idea of a joke, but Stanford researchers believe it may be one of the best dieting methods yet discovered.

Their conclusions are based on preliminary results of a correspondence course for overweight people, attempted for the first time last fall in Monterey.

Dr. Todd Rogers, senior research fellow at the Stanford Heart Disease Prevention Program (SHDPP), says the idea originated several years ago when a community survey showed that most people prefer to lose weight in privacy (rather than classes), using printed materials as their guide.

The survey also revealed that respondents' number one personal health concern was overweight. This is not surprising, Rogers says, considering that the average American adult is above ideal weight.

The home-study course developed by the researchers, called "Drop it off--Weight Loss by Mail," was offered through the Monterey Peninsula College (MPC) for academic credit and a registration fee of $7, and was open only to residents of Monterey. It is being repeated this semester for a new group of Monterey participants.

The course is part of the SHDPP's "five city project," says Rogers, a heart disease risk reduction program based in two "education communities"—Salinas and Monterey, and three "reference communities"—Modesto, San Luis Obispo, and Santa Maria. The project is directed by Dr. John W. Farquhar, professor of medicine at Stanford.

"Our goal in this particular course," Rogers says, "is to reduce the amount of obesity in Monterey County, which will have a favorable impact on morbidity and mortality due to cardiovascular disease."

Twenty-five percent of last semester's participants, he says, had been diagnosed as having high blood pressure—a fact which spurred them on to take the course.

"From a public health perspective," he continues, "we want to try to help prevent future weight gain too, and encouraging people to think about their lifestyle is an important part of this."

The course emphasizes the importance of good nutrition; that is, not just low calorie but low sodium, low fat, and low cholesterol intake.

Participants receive 15 weekly "lessons" in the mail, with informational materials and homework assignments. They send progress reports to their MPC instructor/coordinator, Vicki Schermer-Kleinkopf, R.N., M.P.H.

"We don't provide standardized remedies," explains Rogers. "We try to get people to adapt the flexible guidelines to their own lives."

Phase one of the course, he explains, covers nutrition, physical exercise, and food management techniques.

Phase two is the more theoretical, problem-solving part represented by its acronym "IDEAS," in which each letter stands for a distinct step. One must *identify* personal problems leading to overweight; *develop* various solutions; *examine* the solutions; *act* on the solutions; and "*see* how you're doing."

-more-

"We're teaching not just weight control skills," says Rogers, "but skills for healthy living."

Phase three, he explains, is the relapse prevention and maintenance portion of the course.

Before embarking on the semester, each participant goes through an initial assessment. While students set their own weight loss goals, the researchers do watch out for people who may not really need to lose.

"And we recommend," says Rogers, "that nobody lose more than 30 pounds in 15 weeks." (The average goal last semester, he reports, was 19 pounds.)

Every student is asked to designate a family member or friend as "weight loss collaborator." Explains Rogers, "This supplies a social support system that is not artificially contrived."

Course participants are asked to make a voluntary deposit of $30. How much they get back at the end is proportional to how often they do their "homework" and attain their weight loss goals.

Rogers says preliminary results of the first "Drop it off" course are overwhelmingly positive. "Our aim," he explains, "was to test the course as a beneficial and cost-effective program, for both the participants and the implementing institution."

"The relative weight loss experienced by participants turned out to be, on average, equivalent to that in high-effort, expensive weight programs," he says, adding that these conclusions do not negate the usefulness of group programs for those individuals who prefer them.

"But this sort of course is able to reach more people, many who couldn't afford or wouldn't attend the other programs available."

Of the 75 people who completed the first course, says Rogers, not one reported dissatisfaction at the end. "Everyone had positive things to say."

On average, he says, the men lost 76 percent of their original weight loss goals. Women lost 50 percent of what they had hoped for.

All in all, by the end of the course Monterey County was 682 pounds lighter than it had been at the start.

Rogers' collaborators in the weight loss by mail project, all of the SHDPP, are: Joel Killen, pre-doctoral fellow from the Department of Counseling Psychology; Roy Cameron, Ph.D., visiting scholar from the University of Saskatchewan; and Elizabeth Weinberger, Ph.D., postdoctoral fellow.

(Editors, news directors: The following story was sent *Business Wire* at 12:13 p.m. Thursday.)

STANFORD—

A tentative contract settlement between Stanford University Hospital and the Committee for the Recognition of Nursing Achievement (CRONA) was announced Thursday.

The pact is scheduled to be presented for a ratification vote on Saturday to the approximately 1,250 registered nurses at the 663-bed hospital who are represented by CRONA.

The tentative agreement was announced jointly by the hospital and CRONA negotiating teams, which had been meeting regularly for about a month.

Details of the pact will be released only after nurses review the proposed package, announced Priscilla Wheeler, chief hospital negotiator, and Hedy Dumpel, CRONA president and chief of the union's bargaining team.

A notice of intent to strike, issued by CRONA Feb. 26, was rescinded Thursday morning, said Wheeler, a staff counsel and the university's chief labor attorney. The notice would have authorized a strike effective March 9.

Dr. James F. Silverman, the hospital's chief of staff, said patient admission procedures were returned to normal Thursday morning. A small number of non-emergency scheduled admissions had been cancelled after the strike notice was issued last week.

Negotiations continued through Wednesday night. A 20-month contract expired at midnight Feb. 28.

Results of the ratification vote are expected to be announced by CRONA by late Sunday.

(**Note:** Neither the hospital nor CRONA plans any further announcements until Saturday's ratification vote)

CAUTIOUS REPORT ON "CUSTOM—TAILORED" ANTIBODY TRIAL

EDITORS: Advance for release AM Thursday, March 4 to coincide with publication in the *New England Journal of Medicine.*

Because of the preliminary nature of this report and the possibility that news coverage could raise false hopes of cancer patients that a new treatment is available, the News Bureau did not initiate coverage of the story. However, because of numerous press inquiries the following release was prepared in order to put the report in perspective. Levy is out of town and is not available for interviews.

STANFORD—

An experimental approach for treating B-cell lymphoma (a type of cancer of the immune system's antibody-producing cells) has produced a nine-month remission in one patient, according to a report by researchers at Stanford University School of Medicine in the March 4 issue of the *New England Journal of Medicine.*

The treatment involved administering a specially prepared monoclonal antibody to a patient with advanced disease, according to Dr. Ronald Levy, associate professor of medicine (oncology) and leader of the Stanford team of researchers.

Over the past year, Levy and his colleagues have administered monoclonal antibodies to ten patients with leukemia or lymphoma, with varying results.

(These antibodies were produced by cells from mice which had been injected with leukemia cells.)

Several of the patients experienced temporary or partial improvements in their cancers. Thus far, only the patient described in the *New England Journal* report has achieved long-lasting remission of disease, Levy said.

Levy suspects that the good results in this one case may be because the monoclonal antibody preparation was "custom-tailored" to recognize this patient's tumor cells through a complicated procedure that took six months to carry out.

However, Levy strongly cautioned against undue optimism about the experimental technique based on this preliminary result in a single patient.

"The improvement of this patient's lymphoma with monoclonal antibody administration is a single observation that must be confirmed in other patients before we can draw any conclusions about the effectiveness of this technique," he said.

"Moreover," he added, "this technique of custom-tailoring antibodies applies only to B-cell lymphomas and not to other types of cancer."

-more-

Levy and his colleagues are now preparing to test the highly specific, individualized mouse monoclonal antibodies in several other patients with B-cell lymphoma. No new patients are currently being accepted into the experimental treatment program, he said.

Because it takes approximately six months to prepare a "custom-tailored" antibody preparation for each patient's tumor, "there are serious constraints to this approach," Levy said.

"If the therapeutic effects can be reproduced in other patients and if effectiveness depends on the specificity of the antibodies, more streamlined procedures for the production of these antibodies must be designed," he added.

Levy pointed out that his work is highly dependent upon advances in basic research which were originally made in a number of different laboratories around the world.

"Much of this research was not performed with a clinical application in mind," he said. "One cannot always predict which lines of research will lead to clinical advances," he added. "That is why we must renew the commitment to the basic research effort."

The production of monoclonal antibodies is based on the 1975 discovery by George Kohler and Cesar Milstein in Cambridge, England, that mouse tumor cells can be fused with antibody-producing cells of the immune system called lymphocytes, to create a new cell called a hybridoma.

Hybridomas inherit the quality of immortality from the cancer cell progenitor, and the ability to produce a specific antibody from the lymphocyte.

Methods are available to select out from millions of hybridoma cells the one that secretes the desired antibody. In this case the desired antibody recognizes a specific protein on the surface of the patient's tumor cells.

The experimental therapy was administered to the patient described in the *New England Journal* article only after all other conventional therapy failed to halt progression of his disease.

The current treatments for leukemia and lymphoma include chemotherapy and radiotherapy. These treatments are effective and widely available, Levy noted. "New experimental approaches for the time being are no substitute for the traditional therapies," he added.

Levy's colleagues in the research are Richard Miller, David Maloney, and Roger Warnke. The research was carried out with grants from the National Institutes of Health, the American Cancer Society, the Howard Hughes Medical Institute.

STANFORD UNIVERSITY MEDICAL CENTER
News Bureau Stanford, California 94305

To: Medical and Science Writers or City Desks

STANFORD—

You are invited to a press briefing organized to discuss "Twenty Years of Research Progress in the Treatment of Hodgkin's Disease" at 10 a.m. Friday, May 7 at the Stanford University Medical Center in Room TE 110, Psychiatry and Behavioral Sciences Building.

The press briefing will be held in advance of a day-long seminar scheduled Saturday, May 8 to report on scientific progress in the treatment of this form of cancer, and to honor some 500 patients who were treated at Stanford during the past 20 years as participants in the experimental trials.

When these trials began in the early sixties, Hodgkin's Disease was a lethal form of cancer. Today, thanks to the efforts of researchers as well as the patients who took part in these trials, there is better than 80 percent survival at five years for all stages of the disease, with 75 percent of the patients permanently cured.

At the briefing Friday, May 7, Dr. Henry S. Kaplan, D'Ambrogio Professor of Radiology, and Dr. Saul Rosenberg, professor and head of the Division of Oncology at Stanford University School of Medicine, will review the progress of the past 20 years, and patients will be available for interviews. Kaplan and Rosenberg pioneered many of the new treatments.

Your reporters are also welcome to attend the scientific symposium, from 9 a.m. to noon Saturday, May 8, 1982 in the Sherman Fairchild Auditorium. This portion of the program is open to the public.

Among the speakers, besides Kaplan and Rosenberg, will be Dr. Vincent T. DeVita, director of the National Cancer Institute, Bethesda Maryland, who will discuss "Advances in Chemotherapy."

The afternoon program from 2 to 4:30 p.m. at Dinkelspiel Auditorium is a tribute to more than 500 of the 800 patients who took part in the clinical trials at Stanford. The program will feature talks by Armand Hammer, chairman of the President's Cancer Panel; DeVita, Kaplan, Rosenberg and Dr. Albert Jonson, professor of ethics in medicine at the University of California, San Francisco, as well as patients. The program will be followed by a reception at the Bowman Alumni House grove. (This program is by invitation only because of the limited seating capacity of Dinkelspiel. However, members of the press are invited.)

If you plan to attend the briefing Friday, May 7, please phone the News Bureau, (415) 497-6911.

Packets of background information will be available at the briefing.

Theodore R. Marmor, chairman of the Center for Health Studies in the Institution for Social and Policy Studies at Yale University, will speak on "Government and Medical Care in North America: Canada's Path, America's disquiet," May 3 at 4 p.m. in Annenberg Auditorium.

Marmor is an advocate of government involvement in health care financing, such as Canada has developed. He has recently completed a comprehensive comparative study of the role of government in Canada and the United States.

He received his Ph.D. from Harvard and taught at the Universities of Minnesota, Wisconsin, Essex (England) and Chicago before joining Yale's faculty. Marmor served as special assistant to the Department of Health, Education and Welfare in 1966 and on the recent Presidential Commission on a National Agenda for the '80s.

The lecture, open to the public, is sponsored by the Consortium for Health Research and Policy.

NURSING RECRUITMENT DRIVE NOT IN VAIN

STANFORD—

Unlike hospitals still facing a persistent nursing shortage, Stanford University Hospital has witnessed a steady decline in vacancies since reaching a high point almost two years ago.

Associate director of Nursing Services Nancy Madsen, R.N., M.S., recalls that at one time, Stanford had over 100 fewer full-time nurses than it needed, and had to close down 20 patient beds.

"That was when we really stepped up our recruitment drive," she says, noting that current nursing vacancies have dropped to a handful—three or four on any given day. Madsen explains that the success of Stanford's effort is due to four major areas of emphasis:

Salaries and benefits—Stanford nurses' salaries, Madsen says, have been highly competitive over the past few years. The most recent two-year collective bargaining agreement, reached in March, gives nurses at the highest skill level with more than five-and-a-half years' experience a base salary of $31,283 the first year. Starting nurses receive a minimum of $21,985.

According to Duane Walker, director of Nursing Services, there are two professional ladders for Stanford nurses to climb: the clinical and the administrative. "That way, nurses don't feel forced to leave the bedside in order to advance," he says.

About 80 percent of Stanford nurses do not work full 40-hour weeks. "And those who work half-time or more still receive full benefits," says Madsen.

"We try to honor requests for flexible schedules as often as possible," she adds. "In the past, hospitals were rigid in keeping nurses to exact shifts. We didn't even consider letting a mother get her children off to school and come in at 9 a.m."

Educational programs—Nursing Educational Services has increased its offerings for both Stanford and regional nurses, and has begun an effort to present special symposia on a national basis.

Nurses who have been out of the work force for some time and wish to return to the bedside attend refresher courses at De Anza College, so they can come back and work at the Hospital.

Another project, the baccalaureate preparation program, has been offered at Stanford to working nurses since last fall through an arrangement with San Jose State University.

-more-

Stanford's postgraduate program in cardiovascular nursing, centered around the north ICU, opened in January. "Our hope," Madsen says, "is that nurses attending the program will be attracted to stay and work at Stanford."

"Our regular research program for nurses," she continues, "has engendered an enrichment and interest on the part of our nurses that is one of those retention factors you can't emphasize enough."

Besides helping experienced nurses attain new knowledge, Madsen points out the importance of helping new nursing graduates gain bedside experience.

A preceptor program teams up the new nurse with an experienced nurse on the floor for a minimum of eight weeks. It follows an orientation, which provides classroom discussion and clinical reviews.

The summer student nurse program is a way of reaching people even before they're ready to join the staff, says Madsen. "It's a definite vehicle for recruitment."

Yet the Hospital has not lowered its standards to hire more nurses, Madsen insists. "To the contrary— the state has been pushing a change because of the perception that on-the-job training is sufficient. This is a concept that we, and many of our staff nurses, are strongly opposed to. We believe formalized education is necessary for nurses."

Boosting morale—"We've involved staff nurses in goal setting, and raised everyone's awareness that we are all recruiters." (The Hospital, Madsen explains, now has three full-time nurse recruiters. Kathryn Stucki and Hazel Leavitt work under the direction of coordinator Karen Richards, R.N.)

Nursing administration at Stanford has conducted job satisfaction surveys in recent years, used regular staff meetings to discuss concerns, and stepped up its publications efforts.

Another forum for nurses' concerns has been provided by various nurse-physician groups around the Hospital. "In these groups, such as the one in the intensive care nursery," says Madsen, "both doctors and nurses have a chance to air their confusions and grievances."

Also a boost to Stanford nurses' morale has been the initiation of a nurse-to-nurse consultation program for stress reduction, developed and conducted by Dr. Ann Baldwin, R.N.

And Nursing Services is starting a newcomers' club, says Madsen, to encourage socializing as well as provide information on housing and other practical matters. "The union, CRONA (Committee for Recognition of Nursing Achievement), is going to take a very active role in that project."

Advertising—"We got involved in 'job fairs' across the country, always emphasizing professionalism and staying away from such teasers as 'Come to sunny California and find the man of your dreams,' " says Madsen.

-more-

To attract nurses to the expensive Bay Area, the Hospital offers temporary housing when they arrive. "We still seem to be drawing very well from the east—the northeast particularly."

Nurse turnover at Stanford over the past six months has been from 17 to 20 percent, says Madsen, a decrease from the rate of about 25 percent a year ago. "We compare very well to most hospitals nationally," she says, citing *RN Magazine's* recent estimate of 40 percent for the national nursing dropout rate.

"We at Stanford are now focusing on retention—what we can do to show nurses recognition and respect so they'll continue to want to stay," says Madsen.

"Friends of Nursing," a new community group, is working to raise public awareness of the professional status of R.N.s—"what nurses really do versus the stereotype or the soap opera variety."

"The efforts of this group will help keep Stanford's name out in front of people," says Madsen.

Does this country still face a nursing shortage?

"I think so," says Madsen, adding, "Even the state of California has to face the fact that with only 19 baccalaureate programs we are not preparing enough new nurses."

The situation is aggravated by the reality that many women today are choosing other careers, as a wide range of professional options becomes open to them like never before.

"Still," says Madsen, "we probably do have enough trained nurses in the U.S. The problem is they're not all working." Her observation is corroborated by the American Nurses' Association's recent estimate that 30 percent of the 1.4 million qualified, nonretired R.N.s in this country are currently choosing not to work as nurses.

"At Stanford therefore," Madsen notes, "we can't afford to blissfully back off now."

STATE REPORT LAUDS MEDICAL SCHOOL'S MINORITY ENROLLMENT

STANFORD—

Stanford University School of Medicine is the model of how to attract and enroll minority medical students, the Office of Statewide Health Planning and Development said Friday in Sacramento.

The office issued its report, "1981 California Health Manpower Plan—Biennial Update," which serves as planning guide to the state government and the legislature.

The report said minorities represented 25.6 percent of the entering class at Stanford Medical School in 1980, marking the third consecutive year of minority enrollment increases in the School.

Minorities also comprised 25.3 percent of the total medical student body at Stanford, the highest among California medical schools.

The report said all California medical schools should adopt minority enrollment goals matching Stanford's 1980 figures, with attention given to Chicano, Black, and American Indian applicants.

(Stanford's 1981 figures show a minority enrollment of 26.7 percent in the entering class: 10 Blacks, nine Chicanos, three Native Americans, and one Hispanic, according to the Office of Student Affairs—Editor).

"Since the University of California is a public tax-supported institution," the report noted, "it is reasonable to expect that it will be more responsive to statewide needs and priorities in the education of physicians than will private schools of medicine."

The report said the UC system is making "considerable progress" at most campuses, and should be expected to achieve Stanford's levels by 1983.

California minority populations are increasing, the report stressed, without any similar increase in minority physicians.

-more-

"Four million-plus minorities living in medically underserved areas may constitute the largest unmet need for health care service and personnel in the state," the report said.

Dr. Marvin Karasek, chairman of the ad hoc committee on minority student recruitment at Stanford, said he is pleased by the report.

But he added, "Besides achieving numerical representation of minority students, the Stanford Medical School's thrust is now to address the problem of underrepresentation of minorities in academic medicine.

"Today there are few professors from minority backgrounds either at Stanford or any other medical school," Karasek said.

"We will seek out minority candidates with strong interest in biomedical research and careers in academic medicine, and increase our efforts to recruit them," he said.

The state health plan calls for racial and ethnic parity in the health professions by year 2000. By parity is meant that the percentage of minority physicians should be proportionate to the minority populations in the state.

To achieve that goal, the report said, California medical schools must significantly increase their enrollment of minority students.

Presently total enrollment of minority students in California medical schools is 12.8 percent compared to a minority population of 29.4 percent.

Percentage-wise minority medical student enrollments in the entering classes for the three-year period 1979-81 were:

Stanford University School of Medicine, 25.5; University of California, Irvine, 21.2; University of California at Los Angeles, 17.6; University of California, San Francisco, 15.5; University of California, San Diego, 14.8; University of Southern California, 10; University of California, Davis, 5.7; and Loma Linda School of Medicine, 4.7, according to the report.

Because of differing class size, however, numerically UC, San Francisco had the highest number of minority medical student body with a total of 100, followed by Stanford with 87, UCLA with 80, and UC Irvine with 77.

STANFORD—

Stanford University Hospital (SUH) will raise room rates 5.9 percent and operating room prices an average of 7 percent effective May 15, the Board of Hospital Directors has announced.

In several common categories, the daily cost for medical, surgical and gynecology services will rise from $276 to $292, $293 to $310 for semi-private, and $337 to $357 for private rooms. The rate is $20 less for patients admitted by community physicians who do not need the services of the hospital's interns and residents.

Daily bed rate increases for other types of services vary. New prices range from $248 for a bed in the obstetrics ward without housestaff service to $1615 per day for the few patients requiring the highest level of intensive care.

The 7 percent increase for operating room prices will vary depending on the type of procedure and will range from no change to 15 percent for a small number of services, said Dan Heath, associate director of finance.

The price changes, approved at the hospital board's April 14 meeting, are designed to compensate for increases in hospital costs because of inflation—including rising labor costs—and also decreases in reimbursement to the hospital from the federal Medicare and the state Medi-Cal programs, said Lawrence G. Crowley, vice president for medical affairs.

A recent survey disclosed that 12 Peninsula and South Bay hospitals lose an average of $164 per patient per day for each Medicare or Medi-Cal patient treated. Stanford, included in the survey conducted by the hospitals, loses an average of $315 per patient per day, according to Heath.

About half of the nearly 25,000 patients cared for annually at Stanford are supported by Medicare or Medi-Cal.

Crowley noted that as a teaching hospital and referral center, Stanford draws a larger share of critically ill patients who cost more per day because they need more services and more nursing care. In addition, Heath noted that the average patient at SUH is sicker than a year or two ago and requires more care, particularly nursing.

Patient revenues make up about 99 percent of the hospital's $177.1 million budget, unlike many neighboring facilities which receive tax support.

Stanford last raised room rates Sept. 1, 1981. The increase then was an average of 12.2 percent.

NURSES' POWER: REAL OR IMAGINARY?

STANFORD—

"Nursing Influence: Shadow or Substance?" is the topic of a workshop to be offered to the public May 14, by the Friends of Nursing, a Stanford community group concerned with fund raising and public awareness.

Topics to be covered in the program include "Power and Diplomacy," "Exercising our Professional Selves," and "Beyond Assertiveness." A question and answer session will follow the presentations.

Key speakers at the workshop—to be held from 8 a.m. till 3:45 p.m. in the Medical Center's Fairchild Auditorium—are Shirley S. Chater, R.N., Ph.D., F.A.A.N., of the University of California; Angela B. McBride, Ph.D., R.N., F.A.A.N., of Indiana University; and Jeanne Flyntz DeJoseph, C.N.M., Ph.D., an assistant director of Nursing Services at SUH.

Eleanor Hedenkamp, R.N., a pediatric cardiovascular nurse specialist who has chaired the planning committee for the program, asserts, "Nursing is changing—not only the public perception of nursing, but nurses' perceptions of themselves. Nurses are beginning to realize their value as professionals and the real power and influence they can exert.

"The goals of this workshop are to explore the extent of that influence—how it is affected by the public perception of nursing, as well as by the nurses' view of themselves, both as professionals and as people."

Upon completion of the program, she says, participants should be able to identify three strategies which individual nurses can use to enhance public perception of themselves as professionals, public perception of the nursing profession, and individual influence or power in the practice setting.

The workshop will be open to the public, and lunch will be served. A fee will be charged. Continuing education credit is available to nurses participating in the workshop.

Attendance is limited, and the registration deadline is May 10. For further information call Chris Lindauer, at 497-5311.

TALKS ON TEENAGERS

STANFORD—

"Adolescence: The Interaction of Physical and Social Development" will be the focus of this spring's Progress in Medicine lecture series, a community outreach program sponsored by the Stanford University Medical Center.

The season will open April 28 with an introductory presentation by Dr. Irving Schulman, professor and chairman of the Department of Pediatrics.

Also speaking will be Dr. Iris Litt, associate professor of pediatrics and director of Adolescent Medicine. She will discuss "What you should expect from your adolescent's doctor," stressing considerations that address adolescent health and well-being.

On May 5, Dr. Ruth Gross, professor of pediatrics and director of General Ambulatory Pediatrics, will speak about "Patterns of maturation: their effects on behavior and development."

Dr. Gurdon Pulford of the Palo Alto Medical Foundation, a clinical professor of pediatrics, will lecture on "Psychosocial stressors of adolescence and their relationship to disease," May 12.

The Progress in Medicine lectures were initiated at Stanford in 1966 by Dr. Joshua Lederberg, then professor and chairman of the Department of Genetics, to provide an opportunity for leaders in academic medicine to share their insights and perspectives with the community.

Lederberg had observed: "The community has little opportunity to be informed of the exciting developments in medicine. Public understanding of these developments is of the utmost importance to social decisions."

This year the series has focused on a single theme—the development of the child. "The Science of Birth" was part one, last fall. "The Child: Optimizing Growth and Development" was the winter's topic.

All spring presentations will take place in the Medical Center's Sherman Fairchild Auditorium, at 7:30 p.m. Admission is free, and seating is limited. There are no reserved seats, and no tickets will be issued. Early arrival is recommended to permit the best choice of parking and seats.

For further information and registration forms, call the Medical Center's Office of Public Events, at 497-6389.

TEENS TO LOSE WEIGHT AT SUMMER CAMP

STANFORD—

Stanford's Behavioral Medicine Program this year is offering a summer weight-loss day camp for teenagers, ages 12—17, on the University campus.

Encouraging campers to take charge of their own weight management, the program will teach them to lose weight safely through eating and exercise patterns that promote permanent weight control.

Intended specifically for teenagers, the camp will allow them to have fun and develop skills while slimming down. Included will be group seminars in behavioral change techniques and nutrition education; aerobic activity, tennis, swimming, and other recreational activities; group lunches on campus; and weekly seminars for parents.

(An important feature of the camp is consistent weight-loss management achieved through the intensive day program combined with parental support at home.)

Faculty will include staff from the Behavioral Medicine Program of the School of Medicine.

Two sessions will be offered, and a fee will be charged. The first session will run from June 21 through July 15; the second from July 19 through August 12. Both will take place Mondays through Thursdays, from 9 a.m. till 1 p.m. Campers may register for one or both sessions.

Early enrollment is recommended, as space is limited. For further information call Dr. Mary Southam at 497-5065.

(Editors: The following embargoed for release at 6 p.m. Wednesday, April 14 to coincide with dinner ceremonies announcing the building's name)

STANFORD—

Stanford Medical Center's $14 million cardiovascular research building, scheduled to be completed in October 1983, was named Wednesday (April 14) in honor of a Chicago surgeon and medical equipment manufacturer.

The Dr. Ralph and Marian Falk Cardiovascular Research Center will house the academic and research programs of the department of cardiovascular surgery headed by Norman Shumway, Frances and Charles Field Professor of Cardiovascular Surgery; and the division of cardiology, headed by Donald Harrison, William G. Irwin Professor of Cardiology.

The building was conceived to alleviate crowded lab and office space faced by Harrison and Shumway, whose programs have been carried out in quarters scattered throughout the hospital, campus and rented office space on Welch Road in Palo Alto.

Shumway, in addition to the widely reported development of heart transplantation, has been a pioneer in the field of pediatric open heart surgery. The department he heads at Stanford performs an average of more than 20 open heart surgeries each week.

Harrison is an authority on cardiac arrhythmias and has developed along with colleagues a variety of noninvasive procedures for early diagnosis of heart disease.

The building is located on the east side of the hospital, between the medical center and Stanford Shopping Center. The two lower floors of the building will provide laboratory space, while the top floor will house offices. Patient care will continue to be provided at Stanford University Hospital or the medical center clinics.

Groundbreaking on the 52,000-square-foot building began March 1, and a formal dinner ceremony was postponed until Wednesday for the convenience of major donors.

Mrs. Falk was the largest individual donor for the project. The amount of her contribution was witheld at her request.

A $4 million grant in 1979 from the Max C. Fleischmann Foundation of Nevada enabled the university to begin planning for the building. A second institutional grant of $400,000 in mid-March from the Conrad Hilton Foundation completed pledges needed for the building. In addition, 10 other gifts in excess of $100,000 were pledged.

For many years Mrs. Falk had supported the work of three researchers—including Shumway. The other researchers are Louis J. Bluemle Jr., president of the Thomas Jefferson University of Philadelphia, where Dr. Falk attended medical school, and Dr. David Skinner, professor of surgery at the Pritzker School of Medicine at the University of Chicago in her hometown.

At the dedication ceremonies, Donald Kennedy, president of Stanford, thanked Mrs. Falk for choosing Stanford as the institution to memorialize her husband, who died in the early 1960s. He was co-founder of Baxter Laboratories, developers of prepackaged intravenous units.

The project was designed by Hellmuth, Obata and Kassabaum Inc. of San Francisco. Dillingham Corp. of San Jose is the general contractor.

STANFORD—

Stanford University Medical Center has been selected to participate in a federal study intended to help Medicare officials decide whether to fund heart transplant operations.

Six medical centers, including Stanford, will share $2 million to conduct the study, said Donald A. Young, acting deputy director of the bureau of program policy for the Health Care Financing Administration.

About $1.5 million will be used to fund a limited and still undetermined number of transplants at the six medical centers, while $500,000 will be used to pay for research into the efficacy of funding transplant operations on a routine basis, HCFA said.

Stanford has maintained that the operations is the only viable medical procedure for a limited number of end-stage heart disease patients who otherwise face virtual certain death within a few months.

Currently, Medicare does not pay for heart transplant operations, although partial treatment costs of some eligible cardiac patients who ultimately receive the operation are funded under the federal program.

Medicare has in the past paid specifically for transplants. Payments under the HCFA-administered program were authorized in Nov. 1979 on an interim basis.

In June 12, 1980, the secretary of Health and Human Services announced that the cost of the transplant operation would be excluded from Medicare coverage pending results of the current study, which is expected to take about two years to complete.

HCFA said recently it had suspended coverage because of insufficient data on such issues as the patient selection process, the basis for assessing safety and efficacy, the longterm social and economic consequences of the procedure, broad ethical considerations, the cost effectiveness of the procedure, and the potential, if any, for substantial expansion in the availability of heart transplantation."

Those issues will be reviewed in the present study, using data both from the records of participating centers and data on the limited number of patients selected specifically for the study, Young said.

Among policy issues, Young said, is the usual requirement of Stanford and some other centers to limit the operation to persons under 55 years of age.

"For example, what consequences does this pose for a society that is aging," said Young. "Is this age discrimination or is there a real medical barrier to safety of performing this operation on older people."

Physicians at Stanford and elsewhere have maintained no rigid age barrier exists for heart transplants. But at Stanford and other institutions, general health, including the effects of aging, are taken into consideration when choosing heart recipients.

Selection criteria are particularly crucial for heart transplants, since the number of operations are ultimately limited by the number of available donors, which are often scarce, Young noted.

-more-

Another public policy issue, said Young, is how hospitals should be chosen to perform transplants if a decision is made to fund the operations.

"There is an unusual situation with heart transplants," said Young, "because many hospitals technically are able to perform the surgery, but it may be that only a small number have the specifically trained staff to provide the delicate followup care to prevent rejection and other complications.

"Among many things, this study will seek to determine if certain centers are uniquely able to provide the necessary care," he added.

Young said the cost of transplants will be explored, "but primarily to determine the differences between centers. It would be inappropriate to focus on whether the cost justified the surgery, and in fact the cost of a heart transplant is less than some other services which are routinely paid for under Medicare."

Critics of heart transplantation have noted that the one year survival rate is about two thirds with nearly half surviving five years. Young said that figure parallels the survival rate of some procedures, including the Whipple procedure (radical removal of pancreatic cancer), for which Medicare routinely pays, since they are deemed effective at improving quality of life rather than simply increasing longevity.

(Another example is cadaver kidney transplants, covered by Medicare. According to the 1977 Human Renal Transplant Registry, one year survival was 46 percent, nearly 20 percent less than heart transplants).

Members of the cardiovascular surgery team which performs heart transplants have contended that the operation can save money for society, because it returns patients to the job market.

At Stanford, the cost of heart transplants average about $50,000 and are paid for in a wide variety of ways, including private insurance money, fund raising efforts, personal finances, and federal research grants.

Stanford has performed some 230 transplants since it became the first center in the United States to attempt the operation in December 1967. Currently, Stanford performs more transplant operations per year—about two dozen—than any other institution.

The other centers selected to participate in the research are the University of Arizona medical Center at Tucson, the University of Minnesota Hospitals at Minneapolis, the University of Pittsburgh School of Medicine, the Medical College of Virginia at Richmond, and Columbia Presbyterian Medical Center in New York City.

Young said the six hospitals chosen to particpate were informed of HCFA's decision in a March 23 letter. Young wrote that his staff would be meeting with officials of each of the institutions in the near future to work out details of the demonstration project.

The six centers were selected from among 12 applicants by an independent team of medical experts. Selection was based on recent experience with heart transplantation and whether the center has extensive criteria to select recipients.

BEDSIDE NURSES CONDUCT RESEARCH IN PURSUIT OF QUALITY PATIENT CARE

STANFORD—

A Stanford nurse noticed that emotions can run high between nurses and their pediatric patients. She wanted to find out more about these special attachments.

Another nurse found that certain patients were more at risk for falling while hospitalized than others. She wanted to know why.

Both, with help from Stanford's department of nursing research, have developed study proposals which may lead to some answers.

"We believe the basic problems faced in nursing care can best be identified by the nurses providing that care," explains director of the Department Dr. Lois Welches, R.N.

Nurses, she says, are not only in a position to collect data, but also to implement significant research findings at the bedside, and to disseminate any new knowledge they have gained. "They can also help to contain costs through research," says Welches.

The Office of Nursing Research was established in 1978. Its projects currently deal with physiological and psychosocial responses to nursing care; and leadership and administrative research.

Already a study to compare treatments of bedsores has resulted in conclusions favoring the use of one product—a transparent elastic which provides a moist wound environment—over another, which combined with the use of heat lamps keeps the wound dry.

The principal investigators, Gladys Kurzik, Alba Palmieri and Linda Simpson, had to periodically assess bedsores treated with each substance for size, depth, redness, drainage and granulation.

Prior to their study, the Hospital had no standard policy for the treatment of bedsores (or "decubitus ulcers") with any particular product.

Their findings have led to plans for a follow-up study to be conducted in a group of area hospitals, including Stanford. "Hearing of our results, a pharmaceutical company asked if we would compare a new, less costly substance of theirs with the one formerly established as more effective," explains Welches. "And they agreed to fund the research."

The hospitals to be involved, along with the Home Health Agency (a visiting nurses association), form a unique consortium of nursing research.

Explains Welches, "During my first year here, I began to realize that because patients stay such a short time in the Hospital, it's hard to get a sufficient sample unless you collect data for years.

"So we invited some of the Bay Area hospitals to join us in our efforts by banding together for larger research projects."

-more-

Presently included in the consortium are: Mount Zion of San Francisco, Children's of San Francisco, Veterans Administration of Palo Alto, O'Connor of San Jose, El Camino, Mills of San Mateo, Children's at Stanford, Santa Clara County Visiting Nurses Association, and Stanford University Hospital.

Any nurses who wish to participate in research, Welches explains, will attend the educational programs offered by Stanford's department.

Two basic courses were launched at Stanford last year. The beginning course, aimed at nurses who have never before conducted research, introduces the concepts and helps nurses to draw up their first proposals. The intermediate course is for those with some prior experience who need to sharpen their skills before embarking on more advanced studies. A statistics course will soon be added.

"We then provide consultation for the nurse throughout the entire research process," says Welches.

"Because our educational program has proven so successful," she adds, "we now count 27 projects either completed or in progress."

One study in the nurseries will compare the bacterial and viral contamination resulting from four different methods of collecting breast milk for hospitalized infants.

The principal investigator, Joanna Ward, R.N., plans with the assistance of two other nurses, Penny Rau and Gigi Harvey, to compare samples of milk collected with an electric breast pump, two types of hand pumps, and manual expression.

Ward hypothesizes that the less equipment is used, the less bacterial and viral contamination will result. She hopes her research will provide the basis for a standardized collection procedure.

Two additional research questions will be asked: how commonly is the contaminant cytomegalovirus (CMV) excreted in mothers' milk; and what effect does freezing the milk have on both CMV and the herpes simplex virus.

This latter part of the study will be funded by the lab of Dr. Anne Yeager, associate professor of pediatrics, who has shown constant support and encouragement of the project since its inception.

"We encourage collaboration with physicians," says Welches. "Some of them like and welcome it."

However, she explains, "Many nurses here and at the Medical School collect data to assist in physicians' research. Some doctors have a difficult time seeing nurses do their own research."

Welches noted that one of the "positive side effects" of the research program has been to boost morale and self-esteem among nurses. "Instead of complaining, nurses, by participating in research, can go to administration armed with the facts. That's much more constructive, and it gains them respect from other professionals."

Some of the nursing studies completed or in progress at the Hospital since 1979 include:

- a comparison of the effects of two types of electrodes on monitor readings of cardiac patients;

- a units survey of dietary problems as perceived by nurses and dieticians;
- an investigation of the needs of parents of critically ill children;
- an evaluation of the chemotherapy certification program for nurses;
- the identification of factors in retention of nursing administrators in the U.S.;
- a look at physical location of childbirth and its relationship to maternal perception of the birth experience;
- a look at external factors influencing the incidence of medication errors by nurses;
- a job satisfaction survey repeated every two years to determine the effects of planned intervention in areas of work dissatisfaction; and more.

All proposals for research, explains Welches, must be reviewed by a Hospital committee made up of nurses from all levels. Projects must also be approved by the Department of Nursing Research, and by Stanford's Medical Committee for the Protection of Human Subjects in Research.

Conducting clinical research at SUH, she notes, is not off limits to nursing faculty and students from elsewhere. And besides to its other outreach activities, the Department is planning its first national research symposium, to be held in San Francisco this coming November.

Because research impacts the quality of nursing care, says Welches, Nursing administration recently placed responsibility for the Nursing Quality Assurance Program with her office. Dr. Marianne Zalar, R.N., is in charge of the program.

Explains Welches, "A quality assurance program is mandated by law. We decided if we really want to know what the problems are on the units and provide assurance to our patients that the care is of high quality, then we ought to combine these efforts with the research program."

In the final analysis, she says, administrative support is the single most important factor in the development of any effort to critically examine nursing practice. "Duane Walker, our director of Nursing Services, accepted his position contingent upon the existence of a full-time position for a doctorally prepared nurse researcher. Nancy Madsen, Duane's associate, and all the assistant directors have been a constant source of support."

She adds, "We continue to identify more questions than solutions. But each solution leads us to a more relevant question as we struggle to provide for our nurses an environment of challenge and searching, which we believe will lead to the ever improving delivery of nursing care."

ALCOHOL SERIES OPEN TO PUBLIC

STANFORD—

The Stanford Alcohol Clinic is presenting a series of three public programs on alcohol awareness, to be held Monday evenings at 8 p.m., in room M112 of the Medical School.

"Alcohol and the Human Body" will be the topic of a talk April 12 by Dr. Dennis Low, a substance abuse fellow at the Palo Alto Veterans Administration Hospital.

On April 19, Dr. Susan Beletsis will discuss "Adult Children of Alcoholics." Beletsis is a clinical psychologist at the Stanford Alcohol Clinic.

A preview showing of the film "The Last to Know" will be presented April 26. The film concerns women's abuse of alcohol and prescribed drugs. Dr. Stephanie Brown, clinical psychologist and director of the Stanford Alcohol Clinic, will introduce the film and lead the discussion afterwards. This evening will be co-sponsored by the Stanford Center for Research on Women.

No fees will be charged, and no registration is required. For further information regarding any aspect of the series, call Emily Garfield at 321-3727.

STANFORD—

Donnie Priest, who lost both feet following a plane crash in the Sierra last January, is to stand in front of home plate Tuesday to toss the first pitch of the Oakland A's season opener.

"(Pitcher) Mike Norris and (leftfielder) Rickey Henderson wrote me a letter," the 11-year-old boy said Friday. "I get to talk with all the players and watch the game." Donnie said he was an A's fan but that Tuesday night's opener (April 6, 7:35 p.m.) against the California Angels will be the first time he's been to one of the Oakland team's games in person.

"They (Henderson and Norris) were really impressed with his progress so far," team spokesman Rick Moxley said of the invitation by the two players.

Henderson, Norris and young Priest had met at a Fresno hospital in early January after the boy had been plucked from the wreckage of the plane, where he had spent five days in subfreezing temperatures. The crash had killed his mother and stepfather, but Donnie had managed to stay alive by huddling in sleeping bags stored in the rear of the single-engine private plane.

Priest was moved to Stanford University Medical Center Jan. 12, where both of his gangrenous legs were amputated the next day at midcalf. When he arrived by ambulance, he was wearing an Oakland As cap.

After Donnie was released from the hospital, he continued in a physical therapy program at Stanford. He was fitted with artifical legs March 12.

"He's doing outstandingly well," physical therapist Sandy Kasura said Friday. "He's walking for short distances without his crutches. He has been playing volleyball from his wheelchair during gym class, and he has been doing his own exercises during gym while the other children do theirs."

Kasura said she expects Donnie to complete his formal therapy program—consisting of three weekly visits—in about a month.

With his artificial legs, physical therapists and doctors predict that Donnie will be able to return to lead an active life, including participation in sports such as swimming, jogging—and perhaps some baseball.

Moxley said the boy is to throw out the ceremonial pitch at the season opener, even if it is postponed by rain to later in the week.

STANFORD—

The Board of Hospital Directors at Stanford has recommended approval of a revised design for the Hospital Modernization Plan (HMP).

Approved unanimously by the 14 of 16 board members present at a special meeting Monday afternoon, May 24, the revised plan will be offered for final approval June 11 to the Stanford University Board of Trustees meeting as General Members of the Hospital.

Dr. Lawrence G. Crowley, Stanford's vice president for medical affairs, said the revised design offers a tighter, more environmentally sensitive design which will enable future modifications or additions if needed either during construction or after the project is completed by a target date of May 1987.

Fundamental changes in the design include the addition of three basements—representing about 30,000 additional square feet—to be used as administrative office space. The project would be redesigned from four to three units per floor. However, reductions in the number of units (or pods) will not substantially alter the size of usable space and will actually increase by 110 the number of beds in use at the main hospital center by allowing closing of more beds at the Hoover Pavilion annex.

The HMP is intended to provide more modern and comfortable care via technological improvements and increased floor space per patient beds. Only a handful of additional beds will be added to the current licensed capacity of 663, and this is expected to accommodate patient care needs through the 1990s, Crowley said.

Elvia Garwood, HMP director, said the three-pod plan allows for more open space in the area because it is more compact. The previous design would have required building over Blake Wilbur Drive, a move which would have required restructuring traffic flow in the area.

"We believe that this plan not only will provide us with the optimum potential for longterm expansion and remodeling," said Crowley, "but it will enable us to enhance our role as a good neighbor to the surrounding communities by improving traffic flow and providing an even more aesthetically pleasing development than originally contemplated."

If approved by the General Members on June 11, the revised plan authorizes a construction budget of $71.4 million and a total project budget of $123.9 million. Originally, the General Members, the corporate overseers of the hospital, approved a construction budget of $67.8 million and a total cost of $114.8 million.

STANFORD—

Spyros Andreopoulos, the Medical Center's public information officer, has been appointed director of the Center's new Office of Communications.

The announcement was made May 20 by Dr. Lawrence Crowley, vice president for medical affairs. Andreopoulos' appointment is effective immediately.

The Office of Communications has overall responsibility for the organization and conduct of both news information and public relations activities for the entire Medical Center, including the School of Medicine, the Hospital and the Clinics, Crowley said.

In making the announcement, Crowley noted that the Medical Center is entering a new phase of development, one aspect of which includes the Hospital Modernization Project. A stepped-up program of public information is an essential component in this new era of Medical Center activities, he said.

"It is encumbent on all of us to help create a well-coordinated communications program directed towards improving public understanding of the needs of the Medical Center and its achievement and value to the local and national community," Crowley said.

"Spyros Andreopoulos is well known to all of us in his position as the Medical Center's director of public information for 19 years," Crowley added. "He is ideally suited for this expanded role as director of the Office of Communication and coordinator of all communications activities in the Center."

As director of communications, Andreopoulos reports directly to the vice president for medical affairs and is a member of the Medical Center's administrative policy group.

He will also chair a " communications coordinating council" that includes the directors of the offices of Hospital Community Relations, Medical Center Public Events, News Bureau, and Development, as well as a representative of Clinic administration.

Andreopoulos, a native of Greece, was assistant director of information services for the Menninger Foundation in Topeka prior to joining the Stanford Medical Center News Bureau in 1963.

STANFORD—

Aaron Smith, a Stanford social worker since 1969, has been named the 1982 Thomas A. Gonda Employee of the year.

Smith, who serves in the cardiac care unit of Pediatrics, was presented with the top employee award at a May 18 banquet ceremony by Dr. Thomas A. Gonda, a former director of Stanford Hospital and the man for whom the annual prize was set up to honor in 1975. Gonda currently serves as chairman of the Department of Psychiatry and Behavioral Sciences in the School of Medicine.

The Gonda Award winner was selected by a committee from among 49 persons nominated by fellow employees.

"The patients and families just love Aaron Smith and think the world of him," said director of Hospital Personnel Management Don Thomas. "He is warm and giving."

One nomination letter said, "He'll return to the Medical Center at any hour of the day or night to help a family in crisis."

Smith is co-founder and chairman of the board of the Mid-Peninsula Sickle Cell Anemia Foundation. He also serves on the scientific advisory committee for the National Association for Sickle Cell Disease. His research has included a three-year study on the impact of leukemia on the family unit.

Colleagues praised Smith, a father of two, for being a very family-oriented person and a deeply caring, compassionate human being.

"For once I'm speechless," said Smith during an acceptance speech at the awards banquet. "All I can say is thank you."

In addition to the Gonda Award, five other special awards (plaques) were given to runners-up at the 24th annual Hospital awards banquet.

These winners included Rita Klier of the phlebotomy lab; Richard Peterson of Transport Services; Rosie Rice of Patient Admitting Services; Rhetta Morre of Nursing Services; and Victor Hupman of the Print Shop.

Also, an award was presented to Lauren Fuentes in honor of her late husband Alex, who drowned in a small boat accident last February. Fuentes was regional operations manager at Hoover Pavilion. Jean Bronstein, assistant director of Nursing and a close working colleague of Fuentes, presented the memorial award.

In addition to the awards, over 400 Hospital employees attending the event received pins or other engraved items honoring five to 30 years of service. Retirees with 20 or more years of service were honored as well.

STANFORD—

Dr. Norman Shumway, professor and chairman of Cardiovascular Surgery, and Dr. Paul Berg, professor of biochemistry and 1980 Nobel Laureate, are scheduled to deliver the convocation addresses at Stanford University Medical School commencement exercises June 13.

The two Stanford faculty members were selected as noted spokesmen, one from more of a clinical perspective and the other from basic sciences. They were chosen by a vote of the students in the graduating class.

Dean of the School of Medicine, Dominick P. Purpura, will also speak at the ceremonies, which are open to all members of the Medical School community.

In addition, members of the graduating class of medical students will present special awards to selected faculty members.

The Office of Student Affairs is expecting over 125 Medical School graduates this year, according to student affairs director Diane Winkle. These would include 81 graduates of the M.D. program, 24 graduates of Ph.D. programs, 33 masters degree recipients (including 27 physical therapy graduates), and 12 diplomates from medical microbiology, who are receiving B.S. degrees.

Medical School students will first participate in Stanford University's 91st annual commencement, at 10 a.m. in the Frost Amphitheater.

Then, the Medical School ceremony is to be held at 2 p.m. at Alumni Green, following a 12:30 noon reception in the Dean's Courtyard. After the ceremonies, a champagne toast will also take place at the Dean's Courtyard.

Students are asked to let the Office of Student Affairs know how many family members plan to attend the ceremonies. For further information, call 497-6951.

STANFORD—

Dave (not his real name) comes to Stanford Hospital every five weeks to receive chemotherapy treatment for bone cancer. He's a hefty man, but after four and one half years of the treatment, he's lost five inches off his former height of six feet two inches. He "eats like a horse" for about two weeks, to combat the effects of the chemotherapy. He tries to diet the remaining three weeks, but his weight is up to 265 lbs. Dave needs to lose weight—the opposite of most cancer patients—and has a lot of questions about how to go about it.

Jane (not her real name) is about to begin treatment for a tumor in her stomach area. She'll be coming to Stanford every three weeks for chemotherapy, then radiation as well. She's never had much problem keeping her weight within normal range. She's followed a few health food fads, but, unsure of what effects to expect from the treatment, has a lot of questions about nutrition in general.

Dave and Jane can get answers to all their questions at unique workshops offered by Stanford Hospital's dietetics/nutritional department. The weekly sessions provide outpatients being treated for cancer the opportunity to learn about their individual dietary needs. With the help of a hospital dietician, they also develop a plan to achieve and maintain a high nutritional level in order to obtain full benefits from the cancer therapy.

Good nutrition is especially important for cancer patients undergoing therapy. A proper diet enables them to withstand the treatment for longer periods of time, reduces their susceptibility to infections, and in general, makes them feel more energetic. The treatment can cause patients to experience a number of side effects—loss of appetite, nausea, vomiting, dry mouth and throat, constipation, or diarrhea—at various levels of severity. If these side effects interfere with the patient to the point of lowering their nutrition level, treatment may have to be stopped. *Nutrition for Cancer Patients*, which is handed out at the workshop, explains how to cope with the side effects, and how to keep up the nutrition level.

-more-

2-2-2

The dietician leading the informal workshops discusses why it is important to eat well. She has the patients fill out a form with everything they eat in a typical day. She then analyzes it with them, explaining the importance of each item in terms of it's caloric, protein, liquid content, and the food group in which it falls. With this the patient can see exactly what they lack, or of what they have too much.

Pat Kearny, the dietician working with Dave and Jane, stresses how important it is to let the patients arrive at their own answers. "Most patients have very poor nutrition backgrounds when they come in," she says. "If we just told them what we thought they should do, they'd go home and forget every word. But when they figure it out, it sticks."

Dave, for instance, drinks a lot of cranberry-apple juice, to help break the monotony of drinking so much liquid, which is essential. When Kearny points out the high caloric content of the juice, Dave is amazed. "I've just got to drink something else with fewer calories," he concludes. Kearny smiles her approval, and suggests water with lemon, or perhaps, iced tea.

Jane, on the other hand, asks a lot of questions about health food supplements, of which she takes quite a few. Kearny tells her they are most likely useless—perhaps even harmful since the content is not known. "Our biggest fear is that patients are throwing their money away on some 'magical' health food cure," she says. She tells Jane to concentrate on eating a balanced, high-protein, low-fat diet instead. Jane leaves, relieved of some of her anxiety of what the treatment will bring.

The patients are charged a nominal fee the first time they come to the workshop, but are encouraged to come back whenever they have a question, or even just to hear a supportive word. Many patients do come back again and again, Kearny says, allowing the dieticians to see the effectiveness of the workshops.

"The cancer treatment is devastating, but the worst thing is if the patients loose weight and treatment has to be stopped," she adds. "If we can help patients get through it just a little bit easier, then its worthwhile."

MEDICAL ALUMNI REUNION 1982

STANFORD—

Nightwatch: New Perspectives on Sleep Disorders and their Treatment will be the major focus of this year's medical alumni reunion day, to be presented June 5 by the Stanford School of Medicine's Alumni Association.

In the afternoon, a special feature on cancer patient care will complete the day's presentations.

The program, open to all faculty, students, and alumni, will open 8:15 a.m. in the Fairchild Auditorium.

The morning speakers on various sleep-related topics will be Dr. William Dement, professor of psychiatry, director of Stanford's Sleep Disorders Center, and president of the Association of Sleep Disorders Centers; Dr. Vincent Zarcone, Jr., professor of clinical psychiatry; Gary Richardson, a medical student and director of the chronobiology program; Dr. Christian Guillemenault, associate professor of psychiatry; and Dr. Laughton Miles, clinical assistant professor in Psychiatry and medical director of the Sleep Disorders Center.

The morning program will include a Science Day Poster Exhibit, illustrating student projects in investigative medicine. The morning program is acceptable for continuing medical education credit. A certificate of attendance will be available on request.

A 12:30 luncheon will be held at the Faculty Grant Courtyard. This will precede the Alumni Association Annual Meeting. A keynote address will be presented by Dr. Dominick Purpura, dean of the School of Medicine.

The 3 p.m. presentation entitled "A New Concept in the Total Care of the Cancer Patient" will be followed by a guided tour of the Debbie Probst Oncology Day Care Center. Speakers will be Dr. Charlotte Jacobs, assistant professor of medicine and director of the Oncology Day Care Center; and Dr. Saul Rosenberg, professor of medicine and radiology and chief of the Division of Oncology.

At 5 p.m., cocktails will be served at the Stanford Faculty Club. At 7, reunion dinners for the 50th year class (1932) and the 25th year class (1957) will be held. Also, the classes of 1937, '42, '47, '52, '62, '67, and '72 will gather for dinner at various locations.

Registration materials for the day's events may be obtained by calling 497-5064. Reservations should be returned by May 28.

STANFORD—

Although Stanford has the highest percentage of minority students among California's medical schools, it should nevertheless seek more minorities interested in academic medicine, the faculty senate has recommended.

A $360,000 scholarship fund and the hiring of an assistant dean for student affairs to identify and lure outstanding minority students who are headed for academic careers was specifically recommended by the medical school faculty senate to augment Stanford's existing recruitment efforts for minoritiesu.

The proposal, adopted April 30, was sent to Dean Dominick P. Purpura who would be charged with its implementation.

A Committee on Minority Student Recruitment concluded in a report presented to the faculty senate that the proposed $360,000 funding would be sufficient to pay for 10 students a year for three years.

Students accepted for the program would begin a research project during the summer after finishing undergraduate training and would continue to pursue their research through their first and second year.

By providing students the funds and opportunity to begin their research early, the committee said it hopes to prevent research oriented minority students from being wooed from Stanford to other major institutions.

A particular goal of the program, the committee suggested, is Stanford's Medical Science Training Program, a five-year research track leading to both the M.D. and Ph.D. degrees. The committee noted that in the past three years, the only minority student accepted for the MSTP program chose another university. (Although minority students had been admitted to the select program earlier, including a black medical scientist graduating this June).

The committee had sent questionaires who were accepted at Stanford in 1977 through 1981 but who decided to attend medical school elsewhere. Thirty-six percent said they chose to go elsewhere because of cost or financial aid.

Minorities comprised 25.3 percent of the total medical student body at Stanford, the highest among California medical schools, according to an office of Statewide Health Planning and Development report issued April 23. Stanford's own figures show that the 1981 entering class showed an increase in minority (blacks, Hispanics and native Americans) enrollment, 26.7 percent of the 86-student class.

But Marvin Karasek, associate professor of biochemistry and chairman of the Committee on Minority Student Recruitment, said simply increasing the numbers of minority students is insufficient.

"Besides achieving numerical representation of minority students, the Stanford Medical School's thrust is now to address the problem of underrepresentation of minorities in academic medicine. Today there are few professors from minority backgrounds either at Stanford or any other medical school.

"We will seek out minority candidates with strong interest in biomedical research and careers in academic medicine, and increase our efforts to recruit them," Karasek said.

In addition to Karasek, the committee included Roger Peeks, a physician specialist in general internal medicine and assistant director of the admissions office; and Carla Shatz, assistant professor of neurobiology.

Editors: The Heart Research Foundation has informed us that Shumway will be available to the news media 2 p.m. Tuesday, May 18, at the Mount Sinai Medical Center, NYC. He will discuss with reporters his work with heart and heart-lung transplantation.

STANFORD—

Heart surgeon Norman E. Shumway, professor and chairman of Stanford's department of cardiovascular surgery, has been named the 1982 recipient of the Heart Research Foundation's International Recognition Award for his "distinguished pioneering contributions to cardiac surgery, including transplantation of the heart and lung."

Shumway will be honored during a dinner Tuesday evening, May 18, at the Helmsley Palace Hotel in New York City.

At Stanford, Jan. 6, 1968, Shumway performed the first human heart transplant in the United States. Since then, Shumway and his associates have performed a total of more than 230 heart transplants. More than 90 patients have survived until today, four of them for 10 or more years.

In March, 1981, Shumway's team was the first to overcome complications in the transplantation of both the heart and lung. Since then, six heart disease patients have received heart-lung transplants, and four (including the first patient) have returned to active work and family life.

"Dr. Shumway has earned admiration from both the medical profession and the general public," said Philip Zimmerman, president of the New York based foundation, in announcing the award. "The Heart Research Foundation, which supports and encourages research into the diagnosis, treatment and prevention of heart disease, believes his work dramatically demonstrates the progress being made in efforts to conquer heart disease."

Dr. Richard Gorlin, chairman of the Heart Research Foundation's Medical Committee, said one remarkable aspect of Shumway's work is the increase in survival rate for heart transplant patients during the past decade. Presently, about half of all transplant patients can expect an additional five years of life.

Shumway is the third recipient of the Heart Research Foundation's International Recognition Award. In 1980, the award was presented to Dr. Peter Rentrop of Mount Sinai Medical Center in New York City. Dr. Burton E. Sobel, of the Washington University School of Medicine in St. Louis, Missouri, received the award last year.

STANFORD—

The division of cardiology at Stanford University Medical Center and Hewlett Packard Company have expanded their ongoing research collaboration with a contribution from HP for basic cardiovascular research and an agreement to hold joint development meetings for discussing future projects.

In an April 30 letter, Emery Rogers, chairman of HP's National Grants Review Board, told cardiology division chief Donald C. Harrison that a $250,000 annual contribution for three years is "contemplated in recognition of the increasing importance of corporate support of academic research."

Gary Steinman, technical director of the cardiology division, said the only restriction on the contribution is that it be used for basic cardiovascular research at Harrison's direction. He said the funds would be used in the general areas of engineering, bio-engineering and computer science.

The purpose of the developmental meetings is to identify specific research projects to be undertaken with contract support from HP.

Harrison said developmental meetings will enhance an ongoing relationship of research contracts and informal knowledge sharing which already exists between the division and the company.

"It provides a convenient mechanism for entering into separate research contracts with HP and for working together on projects of mutual interest," Harrison said. "Model contracts have been developed to streamline the process of implementing individual projects. We don't have to negotiate a new contract each time a new project is to begin."

During the past 13 years, HP and the cardiology division have collaborated on the development of several medical systems including an arrhythmia monitoring system in use in more than 1,000 coronary care units around the world, and computer-based systems used in the production and analysis of electrocardiograms, ultrasonic images of the heart (echocardiography), and X-ray images of the heart in the cardiac catherization laboratory.

Harrison emphasized that research grants and contracts with industry are especially important now that federal sources of funds are shrinking.

"But perhaps more importantly, support of this type permits the results of basic research to be transferred promptly to the clinical setting where these results can be applied to patient care."

Also, Harrison said these research programs would enhance the opportunity for graduate students and post-doctorals to participate in advanced cardiovascular research.

"It is particularly satisfying that we are to receive support from a high technology corporation which performs important research of its own and is willing to share its knowledge both through collaborative research projects and through informal interaction among our scientists."

THE HODGKIN'S DISEASE SUCCESS STORY: HOW THEY DID IT.

STANFORD—

Stanford University Medical Center—home of some of the most advanced cancer research in the world—will celebrate an anniversary this week with a unique scientific symposium updating progress in Hodgkin's disease and paying tribute to the hundreds of patients who helped make it possible.

The anniversary marks a full 20 years since Stanford launched a series of daring experimental trials to treat patients with both early stage and advanced Hodgkin's disease.

Until that time treatments, mostly with low voltage radiation, were palliative and this cancer of the lymphatic system, which strikes about 8,000 people a year between the ages of 20 and 40, was commonly believed to be incurable.

Today aggressive diagnosis and treatment can lead to better than 80 percent survival at five years for all stages of the disease, according to Stanford's published figures. Seventy-five percent of the patients are permanently cured.

Even more dramatic have been the cure rates in children, with a 96 percent survival rate at 11 years, and with 93 percent of the children never experiencing a relapse.

The anniversary symposium Saturday, May 8, in the Sherman Fairchild Auditorium was organized by two pioneers in the field of Hodgkin's disease, Dr. Saul Rosenberg and Dr. Henry S. Kaplan. It will focus heavily on the work of Stanford faculty members, their past accomplishments and future directions.

And it will include talks by another important figure in the field, Dr. Vincent DeVita, director of the National Cancer Institute in Bethesda, Md.

It was DeVita who in the mid-sixties introduced the concept of clinical trials using a four-drug combination in patients with advanced Hodgkin's. And it was this combination called MOPP, which stands for the first letter of each drug—mustard, oncovin, procarbazine, and prednisone—that in later Stanford trials was used in conjunction with radiotherapy to produce even more dramatic results than those obtained by radiation alone.

But the real stars in the anniversary event, according to Kaplan and Rosenberg, will be the patients. More than 500 of the 800 patients who took part in Stanford's clinical trials, and who are now cured of Hodgkin's disease have accepted invitations to attend.

Clinical trials of new procedures and treatments are conducted only when the benefits are believed to outweigh the risks to the patient. They must also provide information that would be of benefit to society's future patients.

Nevertheless, terminal cancer patients taking part in experimental trials do risk side effects, pain and possible disability for a chance at life. And for this reason, the role each patient has played in making new procedures more effective and safer for the next generation of patients cannot be overemphasized, according to Kaplan and Rosenberg.

-more-

"Many of the best insights, the most productive insights that we have gotten along the way, came from observations in particular patients," said Kaplan. "They taught us new lessons which gave us the new ideas."

It was in the mid-1950s, when Kaplan began treating Hodgkin's patients with orthovoltage radiation and nitrogen mustard in an attempt to cure the disease while it was still localized.

Experience with a handful of cases, mainly those of Dr. Vera Peters of Toronto, suggested that radiation would do the job, but in half the patients recurrences developed in the next chain of lymph nodes beyond the last one that had been irradiated.

Judging correctly that the effectiveness of radiation treatment was limited by the low-powered kilovolt X-ray equipment, Kaplan worked with Prof. Edward Ginston and a group of physicists at Stanford and helped develop the first megavoltage clinical linear accelerator to be made in the western hemisphere.

In the early 1960's Kaplan, using the linear accelerator, was able to deliver large tumor-killing doses of radiation—as high as 4,500 rads—deeper into the bodies of patients with advanced Stage III Hodgkin's. Treatments were spread over a period of up to four weeks and could be tolerated safely by the patients' skin.

(The disease is classified into four stages. When confined to one lymph area, it is classified as Stage I. If it is spread to adjacent lymph regions but is confined either above or below the diaphragm, it is called Stage II. When it involves lymph regions both above and below the diaphragm, it is Stage III disease. Hodgkin's disease that has spread to lung, liver, bone, bone marrow or other tissues is called Stage IV. Each stage is divided into groups A and B according to whether or not the patient experiences weight loss, fever, or night sweats—Editor.)

The procedure Kaplan used is called total lymphoid irradiation. It involved giving massive radiation doses to nearly all the lymphoid tissues of the body, while protecting other vital organs from ill effects by the use of lead shields tailor-made for each patient.

Even though the patients with the advanced disease had no chance of cure, the idea of total lymphoid irradiation was criticized at the time by some of Kaplan's colleagues.

"Radiotherapists of that day had an almost superstitious fear of treating people both above and below the diaphragm with large doses of radiation," Kaplan recalled.

"But today above 40 percent of the patients treated 20 years ago with the so-called radical high dose are still alive. They represent the first group of Stage III patients ever cured."

Success required not only the accelerator, but also other developments. One was the histopathologic staging of the disease, accomplished at the Armed Forces Institute of Pathology by Dr. Robert Lukes. Another was lymphangiography, a diagnostic test developed in Europe. This test uses an opaque dye, injected into the small lymph channels of the feet, to highlight the lymph nodes in the abdomen in X rays.

The Stanford group used lymphangiography routinely for all patients in their clinical trials as well as all other Hodgkin's patients.

"These studies added a great deal to the understanding of the natural history of Hodgkin's disease," said Kaplan. "We succeeded in showing that in probably 90 percent of all cases the disease disseminates as if it originated in a single site and progressed by what we call contiguous spread within the lymphatic vessels.

"It doesn't just appear helter-skelter all over the body. It has a highly predictable pattern of spread, while in the remaining cases, the disease is presumably disseminated through the circulatory system."

As a result, the Stanford collaborators developed an aggressive program against Hodgkin's disease that routinely included laparotomy and splenectomy as well as radiotherapy, with chemotherapy added in the advanced stages as a potential treatment ally.

Laparotomy and splenectomy involve a surgical incision in the abdominal region to remove tissue samples from the liver and lymph nodes near the spine, and to remove the spleen for biopsy.

An important discovery of the Stanford group was that the spleen in Hodgkin's patients was often a site of silent disease virtually undetectable by the lymphangiogram. Another finding was that the cancer spread by travelling from the spleen to the liver and possibly to the bone marrow.

In about 30 to 35 percent of the cases the extent of lymph involvement had been misdiagnosed. With laparotomy and splenectomy added to lymphangiography, the group was now able to determine accurately the extent of anatomic spread of Hodgkin's disease and then properly treat it with intensive megavoltage radiation.

As Kaplan was establishing the usefulness of the linear accelerator, Rosenberg was working with him and pioneering new developments in cancer clinical trials and chemotherapy as director of the Division of Medical Oncology.

"Twenty years ago the field of chemotherapy and medical oncology didn't exist at Stanford and in most places in the world," Rosenberg said.

"This division has grown from one faculty member, in 1965, to more than 65 people today, and is one of the largest in the Department of Medicine."

Rosenberg's interest has been developing protocols to improve the treatment of lymphomas. He helped establish the value of the laparotomy and bone marrow biopsy techniques. Starting in 1968, he began testing with Kaplan the value and role of MOPP treatment in combination with radiotherapy in patients with Stage I, II, III of Hodgkin's disease.

The combined therapy, according to Kaplan and Rosenberg, proved beneficial for many patients, and these series of treatment trials, conducted over a six-year period, improved the survival and cure statistics beyond what they had been.

In 1974 Kaplan and Rosenberg began new studies in which radiation and chemotherapy alternated, less toxic drug combinations were used, and new patterns of radiation and drugs were attempted in patients with the most advanced disease.

Among the less toxic drug combinations was PAVe, which stands for a three drug combination similar to MOPP. It is used as an alernative to MOPP because it is better tolerated by the patients.

Those trials were ended in 1980 and are still being evaluated, but it is clear, according to Kaplan and Rosenberg, that PAVe has proved to be every bit as good as MOPP, and more acceptable to the patients.

Kaplan and Rosenberg are now trying to perfect the powerful treatment programs with even less toxic drug combinations, without adversely affecting the cure rates.

-more-

Instead of MOPP and PAVe, which almost invariably render males sterile and produce the risk of leukemia developing later, patients will be given a combination of the drugs vinblastine, bleomycin, and methotrexate, or VBM for short, after receiving radiation treatment.

Patients in the middle or advanced stages will also be treated with drugs other than MOPP, with MOPP reserved for cases when relapse occurs after initial treatment.

Kaplan's and Rosenberg's major concern now is the patients' quality of life. Even during the early years, radiation therapy was frequently associated with complications in some patients. They included radiation damage to the heart muscle, bone growth abnormalities, acute leukemia, and sterility in both males and females.

Modifications in techniques have prevented many of these from happening today. Children, for example, with Hodgkin's disease can now be treated without the impairment of bone and muscle growth induced by radiation. Kaplan solved the problem by reducing the dose and extent of radiation and adding chemotherapy.

Recently, the group also reported that 20 of 26 women had succeeded in becoming pregnant following treatment for Hodgkin's disease at Stanford, and giving birth to healthy babies.

"It's a measure of our success that in a disease that was once invariably fatal, we now have the luxury of looking into (the quality of life,)" Kaplan and Rosenberg told a reporter recently.

Using, for example, less toxic drug combinations such as VBM is perfectly justified in patients with favorable prognosis, they believe.

"If VBM works it would be a substantial contribution," Kaplan said. "If it proves not to be sufficiently effective, then we have MOPP in the background as a salvage regimen since its efficacy has already been well proved in patients relapsing after treatment of limited disease."

Kaplan and Rosenberg said that the major advances made at Stanford in two decades of clinical trials with Hodgkin's disease patients were based on clinical guesses—and the guesses usually have turned out to be right.

THE HODGKIN'S DISEASE SUCCESS STORY: TWO PATIENTS

STANFORD—

While their classmates faced parties and classes, Mary Murray and Douglas Eads faced the probability of death.

In their 21st year, the two young people learned they had Hodgkin's disease, a once universally fatal malady which attacks the body's lymphatic system.

But almost immediately they also learned of a bold, experimental program which helped them through occasional uncertainty and doubt to achieve more than a decade of cancer-free life.

Although their paths crossed scientifically, Murray, 35, whose married name now is Vidal, and Eads, 38, don't know each other. They were to meet for the first time May 7 at a news conference heralding 20 years of study and treatment of Hodgkin's disease, which usually afflicts victims in their 20s or 30s.

The following day, Eads and Vidal were to meet about 400 other former patients who graduated to a normal life expectancy from uncertain, often uncomfortable, clinical trials during the 1960s and 1970s at Stanford University Medical Center.

Although some of the patients in the trials were not so fortunate, the 400 survivors indicate that from the experimental work started in 1962, Hodgkin's has evolved from an almost invariably fatal disease to one which after treatment leaves 80 percent of its victims free of all symptoms for the rest of their lives. Survival is more than 90 percent for patients who are treated quickly after the first symptoms appear.

Vidal now lives in the Berkeley hills with her husband, Elie, a professor of French literature at Cal State Hayward, and the couple's 5 1/2-year-old twin daughters, Deborah and Anna.

Vidal, a teaching assistant in art history at UC Berkeley, recently completed her Ph.D. exams and hopes to travel with her family to France soon to work on her dissertation.

Eads, a senior administrative assistant for the Fremont city government, met and then married his wife of 13 years, Paula, while completing graduate school after his cancer was controlled. The couple lives in Fremont with sons John, 6, and Daniel, 4.

Vidal, the art historian, and Eads, the public servant, had much in common starting with a suspicious lump initially misdiagnosed by incredulous physicians. They just didn't associate a relatively rare and lethal disease with their vibrant young patients.

"I was going to school (at Cal State Hayward) and working parttime as a secretary in the Foreign Languages Department," recalls Vidal.

"It was early 1969, I was in my senior year. I felt this lump under my arm. . . I never had anything quite like that. An annoying thing that just wouldn't go away."

Vidal said she had night sweats and started requiring more sleep than usual. Later she learned these were common early signs of Hodgkin's, which attacks the lymph nodes and later spreads throughout the body.

"But at the time, it was just this annoying thing that just wouldn't go away."

She thought she had infectious mononucleosis, and at first so did the student health service at her school. But this was ruled out.

Struggling to recall what they next suspected, Vidal laughs:

"They thought I had an infected pore under the skin. They were wrong."

Her family doctor in her hometown of Oakland referred her to a specialist.

"At this point no one appeared in a great hurry to come up with any sort of an answer. I waited a couple of months, and then I went back to see the specialist. At this point he was anxious, and said, 'well I think it's serious; you're going to need some treatment.' "

-more-

Vidal recalled the doctor recommended Stanford as much because the research program provided free treatment as because he felt the major center provided her best hope for what he strongly suspected by then was Hodgkin's.

For Eads, the lump started in the groin area and his family doctor sent him to the hospital for a hernia operation.

It was early fall in 1965, and Eads had been working through the summer before his senior year at San Jose State in a fruit packing house.

"Looking back I may have noticed signs, I might have been a little more tired than usual. But it was nothing really pronounced."

Eads actually was operated on for a hernia. When his doctor found during surgery that it didn't exist, he sewed the patient up and ran a battery of tests. His results came back a lot more quickly than Vidal's.

"I was still in the hospital recovering from my 'hernia' operation. I knew something was really wrong when the doctor walked to the door of my room, paused, and then walked away. He did this twice. The third time he came in and broke the news.

"I guess because he had a son about my age, he got a little more personally involved than usual. He sat down. I remember he had a medical encyclopedia in his hands and he was reading to me about Hodgkin's disease—how it was always fatal within three to five years.

"For about three weeks I thought I had a fatal disease. I don't imagine you could call me passive, but I was resigned . . . .Death is a little bit easier to face when there really is no alternative."

But Eads' doctor hadn't given up, despite the grim news in the medical encyclopedia.

"He checked around and found that they were doing some new things up at Stanford involving extensive use of radiation and chemotherapy, and he put me in touch with the program."

And Eads drove a few miles up the freeway to Stanford, where he entered the research protocol hoping for a reprieve from his death sentence.

On the other hand, Vidal said the realization of her serious condition did not come until she was deeply immersed in the Stanford program.

"I remember during one of my first interviews over there asking, 'What is Hodgkin's disease?' It seems to me someone had told me that if it wasn't cancer it was a first cousin to it."

" . . .The program was always very encouraging. I knew I was very sick and I finally knew that I had cancer. But always there was this attitude from the doctors, 'we have good success and people are being well treated.' "

Vidal's cancer had spread from the lymph node under her arm to other parts of her lymphatic system by the time doctors admitted her to the hospital, where they removed her spleen during a diagnostic procedure called a laparotomy, a surgical opening of the abdominal wall to permit examination of internal organs. The spleen is removed and examined closely in the lab, helping doctors chart a course of treatment.

When the result came back, Vidal started radiation therapy in the early spring of 1969.

"That was the easiest part of the treatment. I would come to Stanford about twice a month.

"I would get badly sunburned, and I lost part of my hair, and I was tired."

"And then I started chemotherapy, and that was rough—at least for me, although I understand that isn't true for everyone.

"The nausea was tremendous." A decade ago, chemotherapy was administered intravenously, and "I would have to go over to Stanford about once every two weeks. Afterward, before I could get across the Dumbarton Bridge, the discomfort became extremely severe."

Perhaps ironically, the months of treatment were kinder to Eads but ultimately riskier.

"I came up from Santa Clara (where he lived) for radiation therapy treatment almost every day for about a month," Eads recalls. "I was in the research group which was not given chemotherapy and my spleen was not removed" during the laparotomy.

Because the effort was experimental, the men who directed the program, Dr. Henry Kaplan, a radiology professor, and Dr. Saul Rosenberg, a professor of medicine and oncologist, weren't sure which forms of treatment would be the most effective.

-more-

Eads, Vidal and hundreds of their generally young fellow patients over the years were told that not all patients would be getting the same treatment.

"At the time I seem to recall that I was grateful that I would avoid chemotherapy.

"But I was lucky." Only about one third of the protocol patients who received only radiation therapy survived. Today, radiation and chemotherapy are usually combined in relatively advanced disease, and the spleen is usually removed as a diagnostic aid.

(Although both Vidal and Eads suffered from an intermediate stage of Hodgkin's, Kaplan said Eads' condition was less advanced than Vidal's and probably would have been treated today without chemotherapy.

"But he was lucky," Kaplan recalled recently, "because his spleen wasn't removed" and thus doctors could not check for a hidden spread in his condition.)

It was during the active treatment stage that Eads was shown just how grim it would be if his treatment failed.

"Very early in my treatment phase I was kept in the hospital for some tests." I'm sure it wasn't intentional, but I was placed in the same room with a guy who was only a few years older than I in his mid-20s.

"He was suffering from very advanced Hodgkin's, and he didn't have long to live. And he knew it. He was crying regularly. I don't think he felt any pain. He just didn't want to die, and I think some of the medication might have had an effect on his emotional state.

"And I thought, 'well, this might be me in a few years.' "

But it wasn't.

Eads and Vidal both completed the active stage of treatment. Although both were tired and felt the uncertainty of whether they were sick or well, both young people were able to find brief diversions in the form of foreign vacations.

Eads said he accepted an invitation to spend six weeks in Colombia where his aunt and uncle were living, "and this was really one of the highlights of my life."

Vidal traveled to France for 2 1/2 months with Elie, whom she had met while working at the foreign languages department at Hayward State. She said he had become her closest friend and confidant during the ordeal of treatment.

But the relatively blissful and trouble-free world of travel predictably ended, and the period of waiting and uncertainty continued.

Patients are considered almost certainly cancer-free after five years, but during that waiting period, symptoms may recur at any time if treatment is incomplete.

Vidal and Eads say the period of about two years after treatment was one of ambivalence, when no clear direction was yet possible.

Vidal finished the last few credits and received her B.A. in political science by taking one or two courses at a time.

"I lived with my younger sister in an apartment for awhile. Then I lived alone. Looking back, I think it would have been better if I had been busier.

Perhaps the most positive outcome of the post-therapy years, says Vidal, is the beginning of her passion for art history. "After I completed courses for my B.A. I took a few art history courses just for personal enrichment. And I was hooked."

Eads also tied up the loose ends to secure his degree while he rested up. Then he went to graduate school in public administration and began work in 1967 as an administrative aide with the city of Saratoga.

Each year Vidal and Eads went back to Stanford for checkups.

And each year they were declared healthy, and each year their odds for longterm survival improved as they moved toward the five-year mark.

As time went by, say both Eads and Vidal, their confidence improved along with an ability to plan for a future.

So when the five-year mark arrived, it was an important but not dramatic occasion.

"I came in for my checkup," Vidal recalls, "and Henry Kaplan just said, " 'well, it's been five years.' It wasn't dramatic, but I certainly was happy to hear him say that."

Eads doesn't recall the benchmark moment. "It was a gradual thing. -more-

4-4-4 "Well, I've got to admit I was pretty nervous each year just before I went in for my checkups, but each year it got less and less, until now I don't really worry about it."

It may have been coincidence, but it also may have occurred partially as a consequence of living cancer-free for several years—major changes occurred in the lives of the two former patients.

It was a bit before the five year mark for Eads, but in 1969 he and Paula were married, and shortly afterward he moved from Saratoga to the city administration in Fremont, the only job change he has made in his career.

Five years after treatment for Vidal was 1975, and in that year she and Elie moved to their present house in Berkeley. A year later she began graduate studies in art history.

Both former Hodgkin's sufferers say the lingering effects of their ailment are minimal or nonexistent.

"If I don't get eight hours of sleep each night I just don't function at peak efficiency," says Eads, "but I'm not really sure that is a result of Hodgkin's.

Vidal says she might tire a bit more easily than before. The removal of her spleen may have left her with a less than normal ability to ward off infection.

But both are active in sports, running several miles several times a week. Vidal plays tennis, Eads plays racquetball and also skis when he gets an opportunity. And both have young children who demand attention and energetic parents.

Vidal's daughters are adopted. She and her husband had difficulty conceiving a child, and this probably resulted from the radiation therapy, she said. Precautions to prevent radiation damage to the ovaries were not as sophisticated in 1969 as they are today, when a majority of women who undergo radiation treatment for Hodgkins are able to bear children.

But it is the possible problems with adoption agencies her cancer may have caused which lingers longer in her memory than her inability to bear children.

"Elie and I had been turned down by one adoption agency and discouraged by others. They never gave a reason, but in each case there were medical forms, and of course I told them that I had cancer. I also explained that it was a long time ago, and I offered letters from my doctors. We will always wonder if my past illness made it more difficult to adopt."

But Vidal says her odyssey for children ended happily with the adoption two years ago of Deborah and Anna from a French agency. The two twin girls were 3 1/2 at the time.

"Right now Elie and I are going about the business of being young parents—at 35 and 55.

"We do all the things young parents do, and it's just great."

Although her cancer is just a lingering memory, Vidal had a particularly tragic reminder two years ago that the battle against cancer—nearly completed for Hodgkin's—is just beginning for other forms of cancer.

"This is really hard for me to talk about," explains Vidal, "but two years ago my older brother died of lung cancer."

She was in France at the time, going through the process of adopting Deborah and Anna, when her brother, who was 40 and had worked in medical labs, died after a short illness.

"I was cured," she says, "but there was no cure for him. It shows that there is a long way to go."

Eads had a less tragic reminder of cancer two years ago. He contracted skin cancer on the side of his face. But it was quickly removed with no after effects.

Eads' plans for the future are tied to the business of living—raising a family, progressing steadily in a public service career. Vidal's plans also are tied to her family and her burgeoning career as an art historian.

It's been more than a decade since they faced a disease which just a few years earlier had been a death sentence.

They have survived to a time when three quarters of Hodgkin's sufferers can expect to have normal lifespans and the potential, like Vidal and Eads, for lives unfettered by disease.

STANFORD—

The federally mandated committees that oversee recombinant DNA research have set a precedent for involving the public in decisions about science and technology, according to a report by two Stanford University scholars in the May 6 issue of *Nature*, a British scientific journal.

These committees represent a possible future model for "the way society will deal with scientific and technological innovations involving potential risks," say Stanford authors Dr. Diana B. Dutton and John L. Hochheimer.

The most innovative aspect of the federally mandated recombinant DNA biosafety committees has been the requirement that two members on each local committee must represent the interests of the community in which the research is carried out, Dutton says. Giving the public a say in how scientific research is conducted is a controversial idea, she adds.

In an attempt to learn how effectively that "direct public voice," has functioned in making science policy decisions at the local level, Dutton and Hochheimer surveyed chairmen of 19 such committees throughout California and 45 "public" non-scientist committee members.

In their *Nature* report, they discuss the varying responses and conclude that, overall, the recombinant DNA committee framework has established a "workable mechanism for public participation in the decision process concerning science and technology."

However, they note that the widely varying modes of operation of committees around the country point to the need for the public voice to be more closely specified.

For instance, the authors report that although federal guidelines state that public members should represent the health and environmental interests of the neighborhood where the research takes place, 25 percent of public members were actually recombinant DNA researchers or biological scientists affiliated with other institutions in the community.

"Although most such scientists were well qualified technically, their qualifications for representing community interests on public health or environmental issues were not evident from their *curricula vitae*," Dutton and Hochheimer say.

And although the guidelines encourage committee meetings to be open to the public, almost half of the California committees held no open meetings, the researchers discovered. Among the 11 committees surveyed that did have open meetings, only five held them on a regular schedule. None of the meetings was publicly announced.

"In committees that had open meetings, however, almost all the chairmen thought they were desirable, for reasons ranging from preventing public misconceptions to informing committee members about community views," the researchers found.

In addition to differences in public representation and access to biosafety committees, Dutton and Hochheimer found considerable variety in overall committee function. For instance, eight of 19 committees held no regularly scheduled meetings. In 1979, about 60 percent of all committees reviewed ten or fewer research proposals—several California committees did not review any proposals while one committee reviewed 68.

-more-

Overall, the California committees approved 96 percent of the research proposals reviewed in 1979. The majority of committees, 11 of 19, rejected none of the proposals considered. And although the federal guidelines mandate committees to include periodic ongoing review of approved experiments, about one-third of 200 national committee chairmen reported that their committees did not carry out this function.

Committees with non-scientist citizen members reviewed about twice as many research proposals during 1979 as those with no lay members, and also spent a larger fraction of meeting time discussing policy issues, Dutton and Hochheimer found. This belies the argument that benefits of public participation come at the cost of decreased efficiency or incompetent review, the two authors observe.

Dutton and Hochheimer identified other areas where committee functions may have been deficient. For instance, in California 13 of 19 committees reported no health surveillance programs for recombinant DNA laboratories despite general agreement that such a program would be necessary to detect low level health effects.

They also found that committees interpreted responsibility for training their members quite differently. Some offered no training at all while others trained their members from a combination of university courses, manuals and laboratory tours.

Overall, Dutton and Hochheimer say, the survey results suggest that "given a chance, public participation seemed to work fairly well. Most community representatives contributed to effective committee performance by broadening discussion and encouraging more critical scrutiny of research proposals. Public meetings appeared to give committees a better understanding of community concerns."

In a sense, Dutton and Hochheimer say, the public role on biosafety committees has been an "experiment in public participation in science policy." They note that an Office of Technology report calls the committee framework "a possible model for societal decision-making on technological risks."

However, in order for such a local regulatory structure to work effectively, "clear minimum standards" for biosafety committees are needed, the researchers stress. "Such standards are vital in a decentralized regulatory system where effectiveness depends largely on local structures and procedures. Without mechanisms for assuring accountability to community interests, public participation in biosafety committees has not been fully tested."

Dutton is assistant professor of family, community and preventive medicine in the School of Medicine, and assistant professor of sociology. Hochheimer is a doctoral student in the department of communication.

Support for Dutton and Hochheimer's study was provided under a grant from the National Science Foundation's Ethics and Values in Science and Technology program and the National Endowment for the Humanities.

FOR IMMEDIATE RELEASE
STANFORD—

Prominent Mexican scholars and professionals in education, industry, finance, the arts, science and technology will give nine free public talks on "Contemporary Mexico: An Inside View" at Stanford Monday through Friday, May 10-14.

Organized by the Association of Mexican students at Stanford, a group of more than 130 graduate students, the week-long program will open with "A Preliminary Evaluation of the Mexican Education Plan: 1976-82" by Jose Angel Pescador, director of the National Council on Education, Public Education Ministry, at 3:30 p.m. Monday, May 10, in the Auditorium of the Center for Education Research at Stanford (CERAS).

Following his talk, Alfonso Rangel Guerra, director of higher education in the Public Education Ministry, will speak on "Higher Education in Mexico: Present State and Perspectives." Prof. Robert E. Ward, director of the Stanford Center for Research in International Studies, will introduce the program, while Prof. Henry M. Levin of the School of Education will moderate.

Salvador Kalifa, director of industrial economy for ALFA Industries, will discuss "Mexican Industry" at 4:45 p.m. Tuesday, May 11, in Bishop Auditorium of the Graduate School of Business. George C. Parker, director of executive education in the School, will moderate.

"The Current Economic Situation in Mexico" will be discussed by Guillermo Ortiz, manager of economic and finances research for Banco de Mexico, at 3:30 p.m. Wednesday, May 12, at the CERAS Auditorium. "The Economic Outlook for the Next Administration" will then be covered by Jose Julian Sidaoui, adviser in economics research for the Banco de Mexico. Prof. Clark Reynolds of the Food Research Institute will moderate.

"Mexican Literature in the Eighties" will be discussed by Gustavo Sainz, director of literature for the National Institute of Fine Arts and Literature, at 3:30 p.m. Thursday May 13, in the CERAS Auditorium. The "Templo Mayor Project" will then be described by Eduardo Matos Moctezuma, anthropologist for the National Institute of Anthropology and History. Moderators will be Stanford Profs. Jean Franco of the Spanish and Portuguese Department, and John W. Rick, anthropology.

"Miguel S. Wionczek, researcher with El Colegio de Mexico, will describe "Problems of Science and Technology in Mexico" at 3:30 p.m. Friday, May 14, in the CERAS Auditorium, followed by Leopoldo Garcia Colin, researcher at the National Autonomous University of Mexico, who will cover "Science and Technology in Mexico: The President and the Future." Prof. Van R. Whiting Jr., Berkeley political scientist, will moderate.

STANFORD—

Dr. Bruno Bettelheim, widely-known child psychologist and visiting professor of education emeritus at Stanford, will give a lecture Friday, May 7 at 8 p.m. entitled "Misconceptions about Freud."

The talk is free and open to the public at Stanford University Medical Center in Fairchild Auditorium.

Bettelheim attracted international attention for his work with emotionally disturbed children.

His lecture is sponsored by the Clinical Faculty Association and the Department of Psychiatry at the Medical Center.

STANFORD—

Doctors have known for years that elderly patients require less surgical anesthesia than younger patients.

Now a Stanford researcher—in cooperation with five colleagues at the UC San Francisco Medical Center—is trying to learn precisely why, in hopes that doctors will be able to administer anesthesia more precisely and even more safely to an increasingly older population undergoing surgery.

Dr. Donald R. Stanski, assistant professor of anesthesiology and medicine (clinical pharmacology), recently received $520,000 to study the effects of barbiturates on elderly patients. These are the drugs, usually thiopental and methohexital, which patients are given to put them to sleep before longer acting inhaled anesthetics are provided.

His study is part of a $2.6 million grant to the six researchers through UCSF from the National Institute of Aging.

Stanski said he hopes to learn whether older people are more sensitive to the drugs. In other words, will an older person's brain be more affected by a given amount of a drug than someone younger? This is called pharmacodynamics.

In order to closely examine the dynamics of drug effects, Stanski said he will carefully monitor the brain waves of patients by using an electroencephalogram (EEG).

The second dimension, he explained, is that in older people, the drugs might actually be metabolized or distributed through the blood system differently than in younger, more active patients. This is called pharmacokinetics, and can be studied by measuring precisely the drug composition of the blood before, during and after anesthesia.

-more-

"Ultimately we will be studying the relationship between EEG and blood levels and what effect that had on the patient in terms of providing the proper level of sleep for surgery," Stanski explained.

This research, he said, is becoming increasingly important as "the surgical population is getting older. What we're seeing clinically is an older and sicker popuation being operated on, and we need to know how to adjust our drug therapy."

Stanski said that proper dosage is especially critical for elderly patients, since they are more fragile. "If we make a mistake, the consequences are of a greater magnitude," he said.

The principal investigator for the project is Edmond I. Eger, professor and vice chairman for research of the department of anesthesia at UCSF. He will lead research on the effects of aging on the pharmacokinetics of inhaled anesthetics.

The other participants, all from UCSF, include Anthony J. Trevor, professor and vice chairman of the department of pharmacology, who will investigate morphine and ketamine. Ronald D. Miller, professor of anesthesia and pharmacology, will examine muscle relaxants, drugs which temporarily paralyze the muscles so surgeons can work effectively.

Michael F. Roizen, associate professor of anesthesia and medicine, will study the effect of aging on cardiovascular and autonomic control. He will be testing the hypothesis that an older person's autonomic nervous system may react differently to pain and physical stress than a younger person's.

Lewis B. Sheiner, associate professor of laboratory medicine, will work in computer modeling and data analysis, assisting the other researchers in computer simulations and models to predict potential results of the experiments.

TEENS—PUZZLED PARENTS, CHALLENGED PHYSICIANS

STANFORD—

Youth is the healthiest time of life.

This popular belief, though true for some, misleadingly assumes all teenagers are health problem-free. The fact is, adolescence presents a wide range of special medical needs only recently addressed as such by the medical profession.

So said Dr. Iris Litt, associate professor of pediatrics and director of Stanford's division of adolescent medicine. She spoke last week on "What to expect of your adolescent's doctor," the first of the spring's public Progress in Medicine lectures.

She said the first opportunity for health assessment of teens as a group came in the late 60's and early 70's, when phenomena like drug abuse, venereal disease, and unwanted pregnancies reached alarming proportions requiring governmental, parental, and medical attention.

"From statistics gathered at that time," she said, "we finally had enough information to form a good picture of the major health problems of teens."

Most of these, said Litt, are associated with pubertal growth. "They are commonly orthopedic, endocrinologic, dermatologic, gynecologic, and dental in nature."

Also, certain cancers and other tumors are more prevalent among teens than other population groups. Hodgkin's disease, said Litt, is most common in late adolescence and early adulthood.

"Infectious diseases of teens," she continued, "include mononucleosis, Rubella (German Measles), atypical measles, gonorrhea, tuberculosis, and toxic shock syndrome."

Problems associated with adolescents' psychosocial development are pregnancy; drug and alcohol abuse; automobile accidents (the leading cause of death and morbidity for teens); depression and suicide; and anorexia nervosa.

"We also have to deal with those teenagers who not long ago wouldn't have survived past childhood, but because of modern medical treatments have made it to adolescence."

These patients, she said, have undergone such treatments as cancer chemotherapy, renal transplantation, and cardiac surgery. "A physician's approach towards them at this stage must take into account all the other issues important to them because they are teenagers."

An example is acne. "We've seen teens with much more serious diseases care most about getting rid of acne."

Certain forerunners of "adult" health problems are also found in teenagers, said Litt. These include hypertension, high cholesterol, cancer of the cervix, and cigarette smoking (the prevalence of which is on the rise among adolescent females).

"But by and large," Litt asserted, "most adolescents are healthy." Therefore, she said, the major role of the doctor consists of maintaining this health and educating teens to become wise consumers of medical care.

-more-

2-2-2

The usual three actors in a "well-adolescent" visit to the doctor, said Litt, are the teen, the doctor, and a parent. Each has his or her own agenda.

Teenagers want to know whether they're "normal"; whether the doctor can tell everything about them through examination; and whether they can count on confidentiality. "Teens are protective of their parents and don't want to upset them if something is wrong," said Litt.

Parents too want to know if their teenagers are normal (with boys the big question is height; with girls, menstruation). They also ask, "Where did I go wrong?"

The physician's major concerns during the "well-adolescent" visit are health screening, prevention, education, role modeling, and vocational counseling.

Prevention may be through immunization, or it may take another form. "Since traffic accidents account for so many adolescent deaths, we as physicians need to take on an advocacy role, as pediatricians have done with baby car seats," said Litt. "We must learn to predict who's at risk of not using a seat belt, and then find ways to appropriately intervene." (It's been found, she said, that nonusers of seat belts are more depressed and suicidal than users.)

"Teens who feel good about themselves and responsible are the ones who identify with the therapeutic goals of the physician," said Litt. "So these are important factors for us to consider."

Education during the visit means the doctor should not only examine, but teach the teen to examine her own breasts, or his own scrotum, for example.

Physicians dealing with teenagers should always keep in mind the developmental tasks faced during adolescence. These, said Litt, include: establishing independence from parents; establishing sexual adequacy; developing vocational and educational goals; establishing a positive self-image; and developing a capacity for intimacy.

"Often the extent of a teenager's rebellion towards his or her parents is directly proportional to the degree of previous closeness in the family," said Litt. "We physicians can help to reassure parents by pointing out the reasons for this natural rebellion, and reminding them that it doesn't last forever."

As for vocational counseling, Litt said, "The aim is to make sure, at an early age, that patients' career goals and expectations are reasonable given what we know about their physical capabilities."

Should teens all have their own doctors, specialists in adolescent medicine? Litt answered her own question:

"First of all, looking at sheer numbers, there aren't enough adolescent specialists to go around. But besides that, I've come to believe that the best doctor for any teen is whoever he or she feels comfortable with, as long as the physician is knowledgeable concerning adolescents."

She didn't always look at it that way, and recalls a time she shuddered at the thought of how a teenager must feel sitting in the pediatrician's lobby surrounded by babies and toddlers.

"But my teenaged sitter made a comment I'll never forget," said Litt. "She said, 'Sometimes when you're sick, you like to be babied.' "

TINY GAS BUBBLES IMPROVE ULTRASOUND DIAGNOSIS

STANFORD—

Tiny gas bubbles swathed in gelatin are helping researchers at Stanford University Medical Center to take improved ultrasound scans of malignant tumors and brain abscesses.

Though tests in humans are still several years away, preliminary animal studies, published in recent issues of *Radiology* and the *American Journal of Neuroradiology* suggest that the bubbles of nitrogen gas may significantly increase the value of ultrasound as a diagnostic tool in noninvasively distinguishing between normal and abnormal soft tissues deep within the body.

Dr. Barbara Carroll, assistant professor of radiology, leads one Stanford team that is refining and expanding the technique for clinical use.

"Contrast agents"- substances taken into the body that absorb or reflect energy waves differently from the tissue that surrounds them - are familiar tools in radiology. Milkshakes laced with barium outline abnormalities in a stomach or bowel that is exposed to X-ray beams. Injections of iodine can detail faulty blood flow in the veins and arteries that serve the heart.

But an effective contrast agent for the ultrasound scan, an exploratory tool favored by physicians for its convenience and apparent lack of side effects, has been elusive.

Ultrasound waves produce images by bouncing high frequency sound waves off soft body tissues, and recording the reflections. The returning echos are timed, analyzed and converted to electrical signals that can be displayed as two dimensional images on a video screen.

Microbubbles have been recognized for a decade as the best enhancer of ultrasound imaging, because they reflect ultrasound waves 10,000 times more efficiently than an equivalent volume of liquid or solid particles.

-more-

But to increase clinical utility, the bubbles should be uniform in size and shape, injectable in measured quantities, and deliverable at precise rates. Bubbles developed by a bay area research team in collaboration with Carroll and other scientists, seem to meet each criterion.

The gelatin-encapsulated microbubbles (GEM) can be precision-made in sizes varying from 12 to 100 micrometers in diameter. Researchers can choose bubble size and density in the gelatin to complement the size of the vessels they wish to image.

Carroll's group has been using predominantly 76-micrometer bubbles of nitrogen gas - each smaller than a pin prick- to elucidate the twisted, turning blood vessels that characterize V2 carcinomas in the thighs, liver and kidneys of rabbits. Nearly 200,000 of the bubbles can be packed into a milliliter dose of gelatin.

A solid when refrigerated, the gelatin becomes a liquid at room temperature, and carries bubbles throughout the site to be scanned. The bubbles are large enough to stay within the vessels to be mapped (instead of migrating into surrounding tissue as liquid contrast agents do), but small enough to avoid vessel clogging.The gas dissolves within five to fifteen minutes, the smallest bubbles disappearing first.

Researchers currently are experimenting with alternatives to gelatin that could lengthen the life of the bubbles, permitting simple injection into peripheral veins, instead of catheterization of major vessels. Ideal bubbles would be small enough and long-lasting enough to traverse vessels from a vein in the arm or leg through the cappillaries of the lung and out into a target organ before dissolving.

Potential uses of the bubbles reach beyond tumor imaging. Dr.Richard Popp, professor of medicine/ cardiology, is experimenting with microbubbles encased in a polysaccharide coating in studies aimed at measuring blood pressure around the heart noninvasively.

Eventually, microbubbles conceivabley could be used to carry chemotherapeutic agents or cancer-fighting antibodies to target tumors, sparing normal tissue, Carroll said. They might also be used to enhance ultrasound hyperthermia treatments of tumors.

Before the therapeutic value of the bubbles can be explored thoroughly, she added, toxicity tests in animals and humans must be completed.

Carroll's research is sponsored by a grant from the National Cancer Institute.

STANFORD—

Donald B. Tower, 39, of Columbia, Missouri has been appointed executive director of the Faculty Practice Program at the Stanford University School of Medicine.

His appointment, announced by Dr. Lawrence G. Crowley, vice-president for medical affairs, will be effective September 1, 1982.

"The FPP is an essential component of the medical center," Crowley said. "It is the base of the clinical practice of the faculty that serves patients throughout the state and the community as well as the teaching programs of the School of Medicine conducted through the Stanford University Clinics."

Tower will be responsible for administrative affairs, business operations, and policy and financial planning for the FPP in close liason with the FPP's executive committee and the vice president for medical affairs.

He will also be responsible for developing and maintaining all aspects of administrative and operational procedures of the FPP and the Clinics.

Tower is leaving his current position as administrator of the University Physicians, a practice group in Columbia, Missouri. He is known for the development of innovative computerized systems in the areas of patient reguistration, physician and hospital billing, and is experienced in the administration of large ambulatory care facilities.

Prior to his present position, he was executive director of Faculty Medical Practice, Memphis, Tennessee; assistant director of business and finance, Arizona Medical Center, Tuscon; and executive assistant director of admissions at the Los Angeles County Department of Hospitals.

Tower received a bachelor of arts degree in public administration from the University of California at Los Angeles, and has done graduate work in psychology at UCLA and in organization and systems design at the University of Colorado.

The Stanford University Clinics consist of about 82 specialty and subspecialty clinics. They recorded more than 134,000 patient visits in fiscal 1980-81, and gross income for the FPP for both inpatient and outpatient services was approximately $34 million.

STANFORD—

Joe McDermott, 22, died early Saturday (June 26) while undergoing a heart-lung transplant operation.

Dr. Stuart Jamieson, assistant professor of cardiovascular surgery and attending physician during the eight hour operation, said the Schenectady, N.Y. man's new lungs "failed for an as-yet unknown cause."

An autopsy was conducted Sunday.

Failure of donor organs is "a remote but nevertheless ever-present possibility during transplant surgery," said Jamieson, a veteran cardiac and heart transplant surgeon who has taken over the heart-lung transplant program from Dr. Bruce Reitz, now chief of cardiac surgery at Johns Hopkins University in Baltimore.

The first of Stanford's six previous heart-lung transplants was performed March 9, 1981 on a 45-year-old Mesa, Ariz., woman, Mary Gohlke.

Four of the first six combined transplant patients, including Gohlke, have returned to active lives.

Examinations earlier this year have led doctors in the Stanford program to comment that the procedure is viable for a select group of patients who otherwise would have no hope of surviving.

The other successful patients include Charles Walker, now 31, who was transplanted May 1, 1981. He exercises regularly and recently began a career in public relations in Northern California.

Barry Davis, 41, Redwood City, Calif., transplanted Oct. 10, 1981, and Darlene Moore Mathern, 37, Waterloo, Iowa, who was transplanted Dec. 1, 1981, are also reported leading active lives.

Karen Wilson, 27, died several days after her July 28 surgery when scar tissue from previous open heart surgery resulted in excessive bleeding.

-more-

Nancy Lassen, 27, Phoenix, Ariz., the most recent heart-lung transplant patient died Feb. 12 after slipping into an irreversible coma. Her surgery was Jan. 20.

An autopsy performed on Lassen has been inconclusive, Jamieson said.

Recent heart-lung transplants have been made possible by the discovery of Cyclosporin A, a fungal derivative. The drug reduces the body's tendency to fight off or reject foreign tissue.

Previous drugs had the adverse side effect of preventing the windpipe from healing, and early attempts at heart-lung transplantation between 1968 and 1971 resulted in a survival rate of no longer than 23 days.

McDermott had been born with a condition called patent ductus arteriosus, a hole between the aorta and the pulmonary artery. Infants in the fetal state ordinarily have such an opening in their heart, but customarily it closes at birth.

The condition generally does not result in immediate symptoms and can go undiagnosed for long periods. In McDermott's case, the malady went uncorrected until he underwent surgery at age 12.

The opening was successfully closed, doctors said, but by that time his lungs were already damaged by pulmonary hypertension, a constriction of blood vessels in the lungs which leads to high blood pressure in the lungs and subsequent damage to the heart.

McDermott's health deteriorated slowly, and he was able to participate in sports, including water skiing. After graduating from high school in Yonkers, N.Y., he went to work as a tire buster enroute to a hoped-for career as a mechanic. But by January 1981 he was forced to quit work when his condition worsened.

Late last year the cardiovascular surgery team decided that he faced almost certain death within a year, and that his only hope was to replace both his damaged heart and lungs.

A memorial service was scheduled for Tuesday (June 29) at Memorial Church, conducted by Father John Hester, the Roman Catholic chaplain at the Hospital.

INVENTORS HALL OF FAME CITES STANLEY N. COHEN

STANFORD—

Stanley N. Cohen, a key pioneer in the field of genetic engineering, was one of four charter members to be inducted into the "California Inventors Hall of Fame" at an awards ceremony Friday in San Francisco.

Professor and Chairman of the Department of Genetics at Stanford University Medical Center, Cohen is being honored for his work with Herbert W. Boyer of the University of California, San Francisco.

In 1980, Cohen, Boyer,and their respective universities, patented a technique that permits genetic material from the cells of animals to be dissected, recombined in new ways, and then spliced into the genetic material of bacteria.

In addition to creating a powerful research tool for analyzing the complex workings of genes, the technique makes possible the construction of "bacterial factories" that can safely produce large quantities of compounds important in medical treatment.

Because, in principle, bacteria could be engineered to produce almost anything created naturally by plant and animal cells, the technique developed by Cohen and Boyer may have significant applications in industries as wide ranging as energy, chemicals and agriculture.

The hall of fame is sponsored by the Philo T. Farnsworth Foundation, a non-profit corporation named for the San Francisco engineer who invented and patented the first electronic television 55 years ago.

Award winners were selected from more than 100 nominees by a committee of Californian representatives of national science and technological societies, who judged the " extent of the effect of the invention on the public welfare and the advance in science and the useful arts in the United States," according to Alice Bryant, coordinator of the awards.

The California project will be modeled after the National Inventors Hall of Fame, based in Arlington Virginia, which honored Thomas Alva Edison as its first member in 1973.

In addition to the citation of Cohen and Boyer, Farnsworth and Ernest Orlando Lawrence will be inducted posthumously into the Hall. Lawrence, a Nobel Prize winning physicist who died in 1958, has been cited by the hall for his development at the University of California, Berkeley, of the "cyclotron," the progenitor of a whole class of accelerators that use intense beams of particles to probe atomic nuclei.

STANFORD—

The Stanford Heart Disease Prevention Program is looking for 30 volunteers with high blood cholesterol to test a new cholesterol lowering agent.

The study's purpose is to test the effectiveness and side effects of Fenofibrate, which has not yet been licensed by the FDA for general use.

The program is optimistic that the agent will offer substantial help in controlling elevated cholesterol.

Subjects, who must be between 18 and 65, will be selected for the 18-month study after a six week evaluation. No hospitalization is required. Selected subjects must have sufficiently high cholesterol levels on three consecutive tests.

The investigation is being directed by Dr. Robert Superko, a physician specialist in the Department of Medicine.

Individuals who believe they might meet the criteria, or physicians who have patients who might qualify, are invited to contact Superko at (415) 497-6254.

STANFORD—

J.M. Stephen Peeps, currently assistant to Stanford University President Donald Kennedy, will join the Office of Development July 12 in a new role as associate director of corporate relations.

Reporting jointly to the director of medical development and to the director of corporate relations, Peeps will organize and implement fund raising efforts in the corporate community for the university, espeically the Medical Center which conducts its own fundraising activities.

Bruce Hinchliffe, acting vice president for development, said the corporate community contributed $15.5 million to the university last year, an 87 percent increase over the 1978-79 contribution.

After earning an A.B. in English "with distinction" from the University in 1974, Peeps joined the Admissions Office, first as assistant director, then as associate director of Undergraduate Admissions. He left Stanford in 1980 to earn a masters' degree in Education from Harvard University before returning to serve as Kennedy's assistant in 1981.

STANFORD—

Dr. Roy Cohn, Atherton, is the new president of the Stanford Medical Alumni Association, and Dr. Donald Prolo, San Jose, is the president-elect for 1982-83.

Prolo's election was announced at the recent alumni reunion held at Stanford University School of Medicine, which coincides with the organization's annual meeting.

Cohn, class of 1933, practices general surgery at Stanford. He has been a member of the association's board of governors, and member of the editorial committee for *Stanford M.D.*, the association's magazine. He has served on the medical school's faculty since 1938, and was the first holder of the Walter Clifford Chidester and Elsa Rooney Chidester Professorship in Surgery until he became emeritus professor in 1975. He succeeds S. Gainer Pillsbury, class of 1957.

Prolo practices neurosurgery in San Jose. He has served on the association's board of governors, and is regional chairman for the south peninsula chapter of the Medical Fund, which provides financial aid for medical students.

In other action, the alumni association recently gave medical school dean Dominick Purpura a gift of $20,000 to use at his own discretion to aid medical students.

VA FUNDS SCHIZOPHRENIA RESEARCH CENTER

STANFORD—

Targeting for research a mental disease that cripples one fourth of all patients hospitalized in the United States, the Veterans Administration has established a Schizophrenia Biologic Research Center (SBRC) at the Palo Alto Veterans Administration Medical Center.

A five year grant of between $230,000 and $250,000 each year will fund the center which will be directed by Stanford University School of Medicine researchers Philip A. Berger and Walton T. Roth, associate professors of psychiatry and behavioral sciences.

"Our goal is to classify schizophrenic patients using biological criteria," said Berger, who has directed the Stanford Mental Health Clinical Research Center for nine years. The "biological criteria" to be researched at the SBRC include studies of biochemistry, pharmacology and brain structure, as well as brain blood flow, psychological performance, and waking and sleeping electrophysiology of up to 100 veterans who are afflicted with schizophrenia.

For two decades researchers have been collecting bits and pieces of the biochemical puzzle that relates brain processes to behavioral disorders.

While definitive answers still are elusive, current theories suggest that an imbalance of one or more of the chemical messengers in the brain that include dopamine, serotonin, norepinephrine and enkephalins may be associated with the devastating set of mental disorders collectively called schizophrenia.

A long term aim of the center, Berger said, will focus on using the biological classification system to predict which patients will respond best to which types of drug and psychological therapies.

While several new lines of research will be explored in SBRC studies, the center's biggest contribution towards finding effective treatments for schizophrenia may lie in the large number of patients it will provide for study under controlled conditions from a wide variety of research angles, said Jack D. Barchas, Nancy Friend Pritzker professor of psychiatry.

As director of the Pritzker Laboratory of Behavioral Neurochemistry, Barchas has been closely involved in research probing the relationship of dopamine to both depression and schizophrenia and has been a pioneer in psychiatric neurochemistry.

He will coordinate the biochemical studies of neurotransmitters and their metabolites in samples of blood, urine and spinal fluid to be done under SBRC auspices.

-more-

Although most of the SBRC studies will be based at the Palo Alto VA Medical Center, an important collaboration with the University of California's Donner Laboratory in Berkeley will focus on recent advances in biophysics using a process (named PETT for Positron Emission Transaxial Tomography) aimed at mapping the flow of blood in the brains of schizophrenic patients.

Still an experimental technology less than a decade old, PETT has been used primarily to detail blood flow in living heart and tumor tissue, but is also "a very powerful tool" in the research of mental disease, Berger said.

PETT scans trace blood flow by recording the radiation emanating from glucose molecules that have been specially tagged with radioactive fluorine atoms, and then injected into the bloodstream to travel throughout the brain. The more active a specific portion of the brain is, the more energy it will need to perform its task. Since glucose is the major energy source used by the brain, researchers studying PETT scans can be confident that the colorful two-dimensional pictures of the brain, composed by computers analyzing the radiation patterns, accurately reflect the energy use of each brain part.

"If schizophrenics have an abnormality in some area of the brain, they might be getting either more or less blood to that area," Berger explained. "We want to see (by using PETT scans) if schizophrenics' regional blood flow is different from normal subjects."

Electrophysiological studies will monitor both sleeping and waking brain wave patterns. Tentative findings from the laboratory of Dr. Vincent P. Zarcone, professor of clinical psychiatry, suggest some schizophrenics show an abnormally high rate of contractions of their middle ear muscles during Rapid Eye Movement (REM) sleep - the period of sleep when dreams most often occur.

Preliminary hints that middle ear muscle activity might be related to severity of schizophrenia or to responsiveness to medication will be one of several types of electrophysiological studies to be followed up in SBRC research, Zarcone said.

In addition to the neuroleptic drugs commonly prescribed to curb schzophrenic hallucinations and delusions, the effects of endorphins - morphine-like substances that occur naturally in the human brain - will be prescribed in double- blind tests controlled with placebos.

Naloxone, a substance sometimes used to treat heroin addicts, which blocks the effects of both opiates and endorphins, also will be administered to patients in an attempt to better understand the role that naturally occuring endorphins might play in subgroups of the disease.

Stanford's SBRC will share data and methods with an analogous center funded by the VA, to be headquartered at the Bronx Veterans Administration Medical Center in New York, Berger said, as well as with the several non-VA-affiliated schizophrenia research centers around the world.

STANFORD—

Stationary exercise bicycles aren't usually part of the gear that Sherpa porters are expected to carry up Mt. Everest.

But such bicycles were needed in research by the 1981 American Medical Research Expedition to the world's highest mountain and so were agonizingly lugged through ice fields to wind-whipped heights.

Results of a variety of high altitude studies conducted during the expedition—which included scientists, professional climbers and local guides—will be discussed by expedition leader Dr. John West, professor of medicine and biophysics at the University of California at San Diego.

West's lecture, "Scientific Expedition to the Top of the World," is free and open to the public Monday, June 21, from 4 to 6 p.m. at Fairchild Auditorium at Stanford University Medical School.

The talk is sponsored by the Department of Anesthesia at Stanford. Dr. Frank Sarnquist, assistant professor of anesthesia, was an expedition member.

Several experiments were conducted at the summit of the 29,028-foot peak by the two physician members who became the 10th and 11th Americans to reach the highest point on earth.

Sarnquist said Mt. Everest offered a unique—and admittedly glamorous—setting to conduct a variety of blood, pulmonary and other high altitude physiological tests, including the bicycle ergometer tests, "which puzzled the Sherpas who carried up the bicycles until we explained what we were trying to do," Sarnquist said.

HMP PLAN RECEIVES GENERAL MEMBERS' APPROVAL

STANFORD—

The design for Stanford University Hospital's Modernization Plan (HMP) was approved Friday (June 11) by the Board of Trustees meeting as General Members of the Hospital.

The plan, or schematic design, was sent to the General Members, corporate overseers of the hospital, after approval May 24 by the Board of Hospital Directors.

The project, expected to be completed in May 1987, has a construction budget of $71.4 million and a total budget, including financing, of $123.9 million.

In Oct. 1980, the General Members authorized a construction budget of $67.8 million and a total cost of $114.8 million.

The increased cost represents the physical modifications and the added cost of finance in today's high interest money market, said Elvia Garwood, HMP director.

The HMP is intended to provide more modern and comfortable patient care via technological and functional improvements and increased floor space per patient bed.

Six neonatal intensive care beds are the only addition to the hospital's current licensed capacity of 663 beds. This is expected to accommodate patient care needs through the 1990s, said Dr. Lawrence G. Crowley, Stanford's vice president for medical affairs.

Twenty-two new operating rooms will be provided to replace the 14 currently in use.

Garwood said the new plan provides for three nursing units per floor in the three-story nursing addition and the addition of basements. A design approved late last year, would have provided four nursing units (or pods) per floor. That design, she said, would have resulted in a modification to Blake Wilbur Drive if the consolidation with Children's Hospital now under study were to occur in the future.

The new plan, she said, also allows for more landscaping and parking through more efficient land use.

Crowley said the revised design offers a tighter, more environmentally sensitive design which will allow for future modifications or additions if needed either during construction or after the project is completed.

STANFORD—

Eighty graduates of Stanford University Medical School received their M.D. degrees last Sunday during the ceremony on the medical school's alumni green.

In return, the graduates honored six professors for excellence in teaching. The Henry J. Kaiser Family Foundation Award for Excellence in Teaching for preclinical students was awarded to Patricia Cross, M.D., professor of structural biology, and Stanley Falkow, M.D., professor of medical microbiology. The Kaiser award for clinical students was awarded to Jon Kosek, M.D., professor of clinical pathology, and Ron Merrill, M.D., professor of surgery. The Arthur L. Bloomfield Award in Recognition of Excellence in Teaching was awarded to William Watson, M.D., professor of clinical dermatology.

At graduation ceremonies for the entire university earlier in the day, Roy Maffly, M.D., professor of medicine, was awarded the Walter J. Gores Award for Outstanding Teaching. The annual award is presented to three professors from the entire university.

Also at the ceremony were students receiving undergraduate degrees in basic medical sciences, and medical microbiology; master's degrees in medical sciences, physical therapy, health services research, and physiology; and doctorate degrees in biochemistry, genetics, hearing and speech sciences, medical microbiology, neurosciences, pharmacology, and physiology.

Physical therapy graduates awarded the Lucille Daniels Recognition Award for Outstanding Contributions to Physical Therapy at Stanford to Katherine F. Shepard, professor of physical therapy.

Keynote speakers at the ceremony were Paul Berg, Ph.D., nobel laureate and professor of biochemistry, and Norman E. Shumway, M.D., professor and chairman of the Department of Cardiovascular Surgery.

Berg told the graduates, "Our expectations for your future accomplishments are no less demanding as when you arrived to Stanford. You have a payback obligation to restore the knowledge you've taken."

On a lighter note, Shumway said the honor of being chosen as keynote speaker was "only slightly tarnished by knowing M.A.S.H. actor Alan Alda was the first choice."

FUNDING FOR BOSWELL BUILDING IMPROVEMENTS APPROVED

STANFORD—

Stanford University Clinics will undergo extensive improvements under a $6.5 million construction and remodeling program approved Friday (June 11) by the Board of Trustees.

The project involves renovation of the first two floors of the Boswell Building, the facility adjacent to Stanford University Hospital where a majority of the 82 outpatient medical clinics will be located.

"This major effort will enable us to anticipate and prepare for technological developments in medicine expected in the coming decades," said David Mendelow, associate dean of the medical school and administrator of the clinics. "We will be able to offer a more comfortable and efficient service to our patients, as well as providing an even more focused educational opportunity for our medical students, housestaff and faculty," Mendelow said.

The project is expected to be completed in the fall of 1984.

About 135,000 patient visits are recorded annually at the clinics, which serve the Stanford Faculty Practice Plan, a university based group medical practice. Clinic doctors include some 234 fulltime university faculty members. Community physicians also care for patients as voluntary medical faculty members.

The clinics are a separate outpatient care facility from Stanford University Hospital since September 1981.

Improvements include completely redesigned and larger patient treatment rooms, achieved in part by construction which expands clinic space into a few feet of what is now the building's courtyard.

To accommodate teaching activities, four major conference rooms and 17 teaching rooms will be placed in the clinics area, said Langston G. Trigg, assistant director of facilities and project manager.

Procedures requiring local anesthesia but not requiring overnight hospitalization will be performed in four special procedure rooms.

"For the past two years we have been analyzing our needs and attempting to see how we might make the clinics a more comfortable place for patients to seek medical treatment," Trigg said.

"For example, among changes will be a shorter journey for orthopedic patients from their clinic to X-ray. The opthalmology clinic, which obviously serves the largest percentage of visually impaired patients, is specifically being placed in an easy-to-find location," he added.

"A lot of changes which superficially might be seen as technical or procedural will in fact make visits to the clinics more comfortable for patients."

For example, Vera C. Waechter, manager of clinic patient services, said that patient registration is being decentralized to four separate areas.

"This will reduce the amount of time patients will have to wait before seeing their doctor, since they will no longer have to check in with a central desk and then with a receptionist at their individual clinic," Waechter said.

-more-

2-2-2

Clinic renovation has already begun, Trigg said, at Hoover Pavilion, where the plastic and reconstructive surgery clinic and the pain clinic will be housed. Portions of these two clinics activities are already at Hoover, a separate Medical Center building which once housed Palo Alto Hospital.

Other clinics to be located outside the Boswell Building are psychiatry, which occupies its own building on the west edge of the Medical Center; neurosurgery and ENT, located next to the Boswell Building in the Edwards Building, and oncology, which is located in the basement of Stanford University Hospital.

"There will be little disruption of patient care during construction because of the staged approach to the project," Trigg said. "Patients will receive information about the location of their clinic during construction at an information booth to be located near the front entrance."

Designers of the Boswell project are Almeter and Finley, Architects of Palo Alto.

Funding is coming from a variety of sources, including at least $3 million from the Boswell Foundation, the original contributors to the existing facility. Medical School and Faculty Practice Plan reserves are expected to account for $2 million.

STANFORD—

New research animal facilities should be built at Stanford University to replace existing facilities which are old and outmoded or temporary, the Board of Trustees was told Friday (June 11).

David Mendelow, associate dean of the School of Medicine, said in a written report to the trustees that an architect is to be hired this summer to begin planning for a new consolidated animal facility estimated to cost between $9 million and $12 million.

The trustees will be asked to approve the project in early fall after the schematic drawings are completed and sources of possible funding have been identified, the report said.

Current facilities, at several locations around the university, received probationary accreditation from the American Association for the Accreditation of Laboratory Animal Care in 1980.

Implicit in the probationary status, said Mendelow, was Stanford's willingness to overhaul its animal facilities.

A tentative schedule calls for completion of project design during the fall of 1983. The facility, to be located next to Fairchild Auditorium on the west side of the Medical Center, would be opened in mid-1985, according to current plans.

The building would be connected by tunnel to the main Medical Center complex, where most research using animals is conducted, the report said.

The Outdoor Primate Facility west of the university has been improved to serve as a longterm holding facility for dogs, farm animals and monkeys and further improvements are contemplated, Mendelow said.

To provide proper care until the new facility is built, temporary buildings have been constructed in back of the museum, and other holding areas are being improved at a total cost of $1.4 million.

STANFORD—

Researchers at Stanford University School of Medicine are seeking 20 female volunteers who are at least 48 years old and who experience regular menstrual periods to complete a study of the changes women undergo as they approach menopause.

Because the study will examine the hormonal changes associated with menopause, volunteers should not currently be taking oral contraceptives or be receiving hormone replacement therapy.

Dr. Jean Dixen, postdoctoral fellow, and Dr. Julian Davidson, professor of physiology, are conducting the research as part of a larger investigation of the links between the psychology and physiology of sexuality and aging.

The current study builds on their recent findings that post-menopausal women approximately 57 years of age show a physiological response to visual sexual stimuli that is different from that experienced by women 10 to 20 years younger. Dixen and Davidson are eager to determine whether the difference is a function of age or of the hormonal changes of menopause.

Understanding the relationship between normal hormonal changes and sexual function is a first step, says Davidson, towards developing effective treatments that might alleviate the insomnia, depression, muscle and joint pain, hot flushes or sexual difficulties that plague some women during menopause.

Women interested in obtaining further information or volunteering for the project can contact Dixen at 497-2432.

SELFLESS SERVICE EXEMPLIFIED BY EMPLOYEE OF THE YEAR

Editors: Photo available upon request if not included

STANFORD—

Clinical social worker Aaron Smith believes that sometimes the best thing you can do for someone in distress is nothing, "rather than to jump right in and do anything."

He speaks with authority, having worked in his field at Stanford University Medical Center for almost 13 years.

Smith, a recent winner of the Hospital Employees' 1982 Gonda Award, specializes in pediatrics, helping young patients and their families to cope with the stressful experience of hospitalization as best they can.

"We encourage parents to stand still for awhile in their anguish," he explains, "and to allow themselves to experience it." Tears, he claims, can be very therapeutic, and some people just need a place to be comfortable letting them flow.

"Some parents think they have to be brave throughout," says Smith. "We can help them to recognize the courage they already have."

Smith speaks of his families with great concern and compassion. For the past eight years he has dealt exclusively with patients in pediatric cardiology and cardiovascular surgery.

"My days are spent with families of children who have had, or may have to have, open heart surgery."

Conducting both individual and family counseling, Smith tries to help people understand what problems they are bound to encounter with a critically ill child, and what sort of outside supports they might need.

"Most of the support I provide is emotional," he explains. "Even the seemingly minor issue of being away from home—for those who have ventured far to be at Stanford—can create enormous stresses for parents and siblings alike."

Smith helps families understand the diagnosis, so that they may explain it to their child. "We also need to explain procedures, such as catheterization, so that everyone is prepared." In this capacity, Smith facilitates communication between the family, patient, and physician.

"I've been fortunate," he says, "since my professional opinion has always been respected by the physicians and nurses I've worked with." Whatever pertinent information he has about a family, says Smith, he shares with the staff.

-more-

Smith also must be familiar with community resources and agencies that can help families when they leave the Hospital. "Sometimes a patient is here for so long that it's very difficult for the family to return home confidently." For this reason Smith and other social workers are heavily involved in discharge planning, in cooperation with other staff.

During hospitalization, they help families with small amounts of financial aid for food, transportation, and lodging whenever really necessary. "We provide some assistance through outside contributions, and through arrangements we have with certain nearby motels and hotels," he explains.

In some cases, families that have been through similar experiences are willing to help out with lodging or other needs.

Smith says the major change in his field that he's witnessed over the past 13 years has to do with approach: "Now that we have a large body of experience, we're acting on it more assertively in our efforts to help people. Since we know what can happen without support, we no longer wait for families to come to us. We can approach them with authority," he concludes.

Some people, he's observed, can end up using a painful experience—even the death of a child—in a creative way. "When we see families later they seem to be okay. And it helps a dying child to know that his family will survive, though suffer a great loss, after his death."

In the past Smith co-led bereavement groups at the Hospital, for parents whose children had died. At the moment he refers these parents to outside groups, though he hopes they will someday be reestablished at Stanford.

It's not hard to sympathize when Smith concedes, "You really have to get away from all this, in order to get back to it." Luckily, Smith has two daughters who draw him away, often enough, to attend their piano recitals up and down the Peninsula.

Angela, 17, is interested in chemical engineering while Amy, 13, wants to be a doctor someday. Smith's wife Anna is also a social worker, for the Child Protective Services of Santa Clara County. The family is involved in social groups and church activities near their San Jose home.

Smith says receiving the Gonda Award at the recent Hospital Employee awards banquet was a total surprise. "I suppose I was nominated because people are impressed that I constantly listen to other peoples' problems—but other social workers do that too," he modestly asserts.

Smith received his masters in social work at Howard University in 1964. He earned a masters in public health at U.C. Berkeley in 1968, and is now working on his dissertation for a Ph.D. in medical sociology from U.C., San Francisco.

He is the social worker advisor to a support group called "Parents for Heart," sponsored by the Santa Clara County Chapter of the American Heart Association. He also serves on both the Mid-Peninsula Sickle Cell Anemia Foundation and the National Association for Sickle Cell Disease.

STANFORD—

In keeping with a long standing tradition, 61 of the 80 medical students graduating from Stanford University School of Medicine this year have been matched to one of their top three choices for internships.

Overall, 48 students will be interning in a university hospital, with Stanford University Hospital receiving 11 graduates.

Also in keeping with past years, the largest number of graduates, 28, will continue their medical training in internal medicine. Other popular choices include family practice, surgery, pediatrics, and flexible internships.

Four members of the graduating class will pursue post-doctoral research fellowships in the coming year.

The medical students' success in the intern matching process is a reflection of their strong clinical performance, according to Dr. Elizabeth Short, associate dean for student affairs, as well as a counseling program that helps them apply for programs most appropriate to their level of experience and career goals.

STANFORD—

A distinguished award to honor Stanford's best and brightest in academic medicine has been created by the medical school's department of medicine.

The award is named in honor of Albion Walter Hewlett, MD, an internationally known professor of medicine and leader in clinical investigation at Stanford from 1916 until his death in 1925.

The Albion Walter Hewlett Award, symbolized by a metal sculpture by acclaimed sculptor Agnese Udinotti of Scotsdale, Arizona, is the brainchild of Dr. Kenneth Melmon, chairman of the Department of Medicine.

The sculpture, unveiled last Thursday in Fairchild Auditorium, depicts "man—his isolation intensified by disease—and the evolution of his integration with society through the intervention of the physician," according to Udinotti and Melmon.

The sculpture will be housed in the hospital's main lobby, together with some of Hewlett's books. A slide presentation, shown at the unveiling of the award, will be included in the display for viewing.

Recipients of the award, to be given at most once a year, will receive a parchment seal depicting several figures from the sculpture, a silver medallion made from the seal, and an undetermined amount of money with which they can select books or journals for the Hewlett Library.

A special committee will choose the recipients from nominations by anyone involved in the Stanford academic community. "Nominees should be living physicians who have some Stanford background and are well-known as dynamic role models for future academicians and practitioners of scientific medicine," according to the department. "They should symbolize the ideal portrayed in the sculpture: the physician of care and skill who is committed to discovering and using biologic knowledge, wisdom, and compassion to return patients to productive lives."

Authoring almost 100 publications were among Hewlett's contributions to medical science. He was among the first to demonstrate the effect of quinidine in cardiac arrhythmias, and to use large doses of digitalis in heart failure. He was known as a great teacher, and a compassionate and skillful practitioner as well. A library-conference room at Stanford is named after him, and 'Hewlett Clubs' exist in Los Angeles, San Francisco, and Oakland.

Hewlett's daughter, Dr. Louise Nixon, who received her MD degree from Stanford in 1951, was present at the unveiling, as were three grandsons, Jim Hewlett, a scientific programmer, Walter Hewlett, who is involved in the computer business, and William Hewlett, a sixth year medical student at Stanford.

Son William Hewlett, of Hewlett Packard Company, was in Europe and unable to attend.

STANFORD UNIVERSITY HOSPITAL SEEKS IDENTITY OF ELDERLY PATIENT

(Editors: The following story sent Business Wire Wednesday, June 2)

STANFORD—

The identity of a man believed to be in his late 70s has stymied Stanford University Hospital officials for 10 days.

"I've worked here for 16 years and this is the first time that we've ever had a live 'John Doe' unidentified for more than a few hours," said social worker Juanita Smith. She has spent the past week making phone calls and other inquiries in hopes of unraveling the mystery of the thin, mustached man of average build who has been occupying a room since shortly after he was brought to the emergency room on May 24.

Smith said witnesses called an ambulance after the man, who has mixed black and white hair, collapsed and fell at the corner of El Camino Real and Oakwood in Redwood City.

He was wearing a navy blue jacket, gray pants "and appeared to have been well taken care of. He didn't look like a derelict," Smith said Wednesday.

He has responded to the Italian language spoken by a medical student and has mentioned the name "Joseph Raffino," although an exhaustive check of local agencies and records has failed to produce a missing person of that name in the area, Smith said. Moreover, she said the puzzling contexts of his conversations indicate he may be referring to another person named Raffino, not himself.

He has told medical personnel that "his wife and son are dead and he lives with some other men," said Elizabeth Taft, director of discharge planning at the hospital.

He had no wallet and only $2 in cash was found on him when he was brought to the emergency room, Smith said.

He was suffering from a minor head injury, although that appeared to have been caused by the fall to the pavement, said Dr. Edward Novotny, a neurology resident who has been caring for the unidentified man. Novotny added it is possible although unlikely that the head injury could have been caused by a mugging.

The man suffered no other injuries and appears to have been suffering from a long-term loss of mental function with the symptoms of senile dementia, Novotny said.

"He has a short attention span and his answers frequently are *non sequiturs* ," Novotny added.

The physician said the man also suffered from dehydration but this has been corrected with proper nutrition.

By Wednesday morning, Novotny said, the man was well enough to be released from the hospital if proper supervision—such as a nursing home or a relative—were available.

Smith said persons who think they might have information about the man's identity are urged to call (415) 497-5091.

WHICH STRESS IS STRESSFUL?

STANFORD—

Just before a dried out alcoholic is ready to leave a detox center, he tells a screening psychologist that his wife just died.

The psychologist—by training and common sense—writes down that the patient has an environmental stress in life and therefore might run a higher than average risk for hitting the bottle and winding up back in the detox center.

But Rudolf Moos, professor of psychology and director of the Stanford Social Ecology Laboratory, thinks more persons, particularly psychiatric patients or others suffering from emotional disturbances, could be helped if health professionals could be provided with more accurate definitions of stress and how people respond to it.

Moos, who also directs psychiatric research at the Palo Alto Veterans Administration Medical Center, is conducting a study to find out how to define stressful incidents and how individuals respond to these pressures.

Moos has received a $295,306 grant from the John D. and Catherine T. MacArthur Foundation to continue his work, "Measuring Environmental Stressors and Coping Resources."

When a patient says "my wife just died," health professionals uniformly regard this as an environmental stress, says Moos. They are trained to make predictions about the patient's potential outcome and to some extent how the person will respond to the situation based on the simple statement, he adds.

But Moos says at the very least we need further information. How long had the widow or widower been married? Was it a loving relationship or a distant one that the patient might in fact be relieved to see ending?

"Before we can accurately screen patients, we need to learn to ask these sorts of questions, then we need to learn how people cope with specific life crises," Moos explains.

The three-year study, he says, will seek to categorize various stresses which ultimately may have mental health implications. The study will then look at how people respond to situations which indeed are stressful, and also how social resources, such as family or friends, affect the response to stress.

After developing ways to measure stress factors and coping resources, Moos hopes to use the information to identify individuals who face the highest risk for a recurrence of such illnesses as depression or alcohol abuse. The information would help clinicians provide preventive measures to increase the chances that treatment will be successful.

The Chicago-based MacArthur Foundation is a private philanthropic organization which provides research funding in such fields as mental health research, education, public affairs, communications, and the justice system.

LEARNING TO LOVE SPIDERS: AN ANTI-PHOBIA PROGRAM

STANFORD—

Jean Oxe realized the severity of her spider phobia about a year ago. The apartment in which she was living seemed to be overrun with them. She got so paranoid, she said, that she would check behind her headboard—where she was convinced they were waiting to attack her—each night before she got into bed. The final thread in the web came one evening when there seemed to be a spider everywhere Oxe turned. "I flipped out," she recalled. She fled her apartment, spent the night at a friend's, and soon after moved.

Oxe said she "broke out in a cold sweat" at the mere sight of a spider. So when a colleague at work pointed out a study being done at Stanford to help people overcome spider phobias, she decided to volunteer. After just a few hours of treatment under the direction of psychologist Lloyd Williams, Oxe was not only cured of her fear, but seemed to enjoy playing with the spider as it crawled on her hands and forearms.

Williams helped Oxe overcome her phobia with a treatment called participant modeling, developed by psychology professor Albert Bandura. By measuring Oxe's, and other subjects', levels of catecholamines, a group of hormones including adrenalin that the body releases in reaction to stress or fear, Bandura and Williams are studying their theory that confidence, or self-efficacy, is a central factor in fear. If an individual can be made to feel confident or in control while in the presence of spiders, for example, the fear will be reduced.

Oxe began her treatment with a number of exercises, such as looking at a spider inside a glass container. Despite her constantly reassuring herself, she balked at putting her hand in the container with the spider. Thus, her level of fear was determined.

She then filled out a form rating her own confidence levels. Statements referring to simply being in the same room as a spider presented no problem to Oxe; she rated herself near 100 percent. When it came to coming in direct contact with the spider however, her confidence quickly dwindled to near zero percent.

-more-

The next step was Williams'. Sitting across the room from Oxe, he told her about spiders: their timidness, their habits, and their nature. He simultaneously let the spider crawl on his hands and forearms. He demonstrated picking up a spider with a cup and a piece of paper, to dispose of it without having to touch or kill it. Oxe sat staring fixedly, looking uncomfortable at the prospect.

"I can't stand the thought of killing the spiders, but I don't want them around either," she remarked. "It's all the little legs running around that scare me."

Oxe was then hooked up to a machine that would measure her catecholamine levels. Williams proceeded to encourage her to put her hand in the bowl with the spider. She was a bit jumpy at the initial touch of the spider, but soon relaxed enough for Williams to put the spider on her hand. Others first use a garden glove. From there, it was just a matter of moments before Oxe and the spider became good friends.

"I'm absolutely amazed. I'm really proud of myself," she exclaimed.

Williams reinforced Oxe's new attitude by having her repeat the exercises with two other spiders. She completed another confidence form, to show her the progress she'd made, and with that, Oxe was "cured."

Oxe is just one of many volunteers Williams and his colleagues are helping while atudying their theory.Even those with seemingly incurable fears are able to overcome them with the treatment. The results should be published by mid summer, Williams predicted, leaving the room.

Oxe however, was long gone. She was going, she said, to find some spiders.

PALO ALTO CITY COUNCIL CONSIDERS HMP RESOLUTION

STANFORD—

The Palo Alto City Council Monday night (July 27) postponed until Aug. 9 a decision on whether to pass a resolution formally supporting the Stanford University Hospital Modernization Plan (HMP).

The resolution is not required for work to continue on the project, but hospital officials are seeking the action as a testimony of support from the council as the HMP faces review by state and county agencies.

"We are seeking the voice of a friend and neighbor who will vouch for us as we move through the governmental approval process in the weeks, months and years ahead," Lawrence G. Crowley, Stanford's vice president for Medical Affairs told the council Monday.

Crowley said SUH plans to seek similar resolutions from neighboring communities in the future.

Councilmember Emily Renzel, who was absent, had written her colleagues requesting a postponement until the council was able to seek assurances from Stanford on several issues, including the issue of access to hospital-based services by community physicians and financial issues relating to the hospital and HMP.

Councilmember Larry Klein, who in Renzel's absence sought the continuance Monday night, said "it was not appropriate" for the council to become involved in disucssions of Stanford finances. But he recommended—and the council subsequently adopted unanimously—his motion that a public hearing be held Aug. 3 to discuss the access question and other issues relating to the hospital's HMP request.

The hearing would be conducted by his council hospital subcommittee which will report back for full council action on the resolution Aug. 9.

Stanford asked the council to approve a resolution saying "the City of Palo Alto supports modernization of the Stanford University Hospital."

-more-

The measure states that approval "does not constitute advance approval by the City of Palo Alto of any of the financial, environmental or physical aspects of the modernization project."

Full public hearings by the city would be held when the hospital seeks a favorable environmental impact report and building permits.

The $123.9 million HMP is intended to bring the hospital up to modern standards and fulfill the patient care and teaching needs of the community and medical center through the 1990s.

"Everything in the plan is necessary for the hospital's survival," Sheldon King, director of SUH told the council Monday.

Paul Cooney, a Palo Alto physician and clinical professor of medicine, told the council that the access question was like the "rock of Sisyphus," an obstacle which in recent years has caused discord between the hospital and some physicians and needs to be resolved.

But Cooney said he favored the HMP: "It's a given. There's no right-minded physician who wouldn't be" in favor.

Geraldine Steinberg, a lay member of the hospital board and former member of the Santa Clara County board of supervisors said "access and the need to modernize are two different issues."

Both she and Walter Arons, a Palo Alto physician who also serves on the hospital board, said that discussions between hospital and community physicians are making progress and should be conducted independently of the HMP question.

The question of access has not involved the admission of patients, since all qualified community physicians may admit their patients to SUH, and Palo Alto residents have priority for elective admissions.

At issue is the question of whether doctors who are not fulltime faculty members may have unrestricted or greater privileges to perform certain procedures in hospital or university operated labs or facilities, such as radiology.

"FEMININE" FIELD OF NURSING OPENS DOORS TO BOTH SEXES

STANFORD—

The nursing profession is ready to welcome more men to its ranks, says Duane Walker, Stanford's director of nursing services.

Though the field is usually perceived as "feminine," Walker insists that any profession can only benefit from the variety of input provided by both sexes.

Still, while society's expectations change and more women enter traditionally male-dominated fields, there is not yet a corresponding rise in the number of males choosing "female occupations" like nursing.

"Nationally as at Stanford," observed Walker in a recent interview, "only about three percent of nurses are men." The profession, he said, is beset with persistent stereotypes—including the idea that it is a secondary career, a step down from medicine.

William Thompson, R.N., who works on NOA (behavioral medicine unit) said the decision to enter nursing was a real struggle for him. "First I had to feel comfortable with my own masculinity."

Mike Lazzeri, R.N., a cardiovascular intensive care nurse, agreed. "I knew I wanted to work in health care, and it came down to a choice between medicine and nursing."

He first resisted nursing for two basic reasons, Lazzeri explained: the economic reality ("...it will hardly make one rich..."); and the traditional image of nursing as "woman's work."

Lazzeri came to grips with his hesitations.

"But it was very hard for me to tell my parents, and ten times harder to tell all the guys I played basketball with." Lazzeri's wife Mary, also a nurse, was "a gentle support throughout," and the others encouraged him as well.

He explained his choice: "The difference between medicine and nursing, as I've always seen it, comes down to an approach to people and how one feels in that approach. Physicians must look at people primarily in terms of data and statistics. While nurses too are concerned with these aspects, they tend to regard their patients primarily as people.

"It's not that doctors don't care as much, but there is definitely a greater closeness allowed for nurses."

Both Lazzeri and Thompson came to nursing in a roundabout fashion. Thompson, a free-lance photographer with a psychology degree, worked at all sorts of odd jobs until becoming interested in nursing. He came to Stanford over two years ago, first working in medical oncology.

-more-

Lazzeri, at Stanford two years, was recruited directly to the cardiovascular intensive care unit, since the nurse shortage at that time necessitated hiring new nursing graduates.

Both intend to remain in nursing, though they may not hold rigidly to any specialization. Explained Thompson, "You can always change areas in nursing. That's what makes it exciting."

Added Walker, "Unfortunately most of the men who *have* entered nursing, thus far, have been pushed into a few areas. These include psychiatry, management, and teaching—all of which keep them further from the bedside."

His own story serves to illustrate: "I loved bedside nursing, but became an administrator because I wanted to have a greater impact on professional issues, and because of the greater pay. Often I do miss the direct contact with patients and families."

How do patients and families, as well as fellow staff and physicians, respond to male nurses?

The answers vary, but the overall consensus is that individual traits, not gender, make the difference in how people feel about their nurses.

As Lazzeri pointed out, "When patients first meet me they take a hard look and then say, 'Fine.' Once they know me they often ask, 'Why are you in nursing? Do you plan to go on in medicine?' "

Agreed Thompson, "With female nurses they don't assume these things."

Both men have noticed that they are referred to, especially by older patients, as "my male nurse," rather than simply "my nurse."

Sometimes a sort of reverse prejudice is found, when people actually express a preference and greater respect for male nurses.

According to Lazzeri, "Being a man does often help me get my foot in the door with the doctors. Then I have to prove myself like everyone else."

Most female nurses, said Lazzeri, agree the profession needs more men, and he has never experienced discrimination in terms of assignments or promotions.

"Let's face it," said Walker. "Anyone who has a problem accepting the opposite sex at work must really be threatened by his or her own insecure sexual identity.

"I'm a caring, sensitive individual, and I'm also a man. I don't have to drive a truck to prove it."

Both Thompson and Lazzeri feel that by simply doing their jobs and being themselves, they're serving to reinforce the concept that anyone with human warmth and intelligence can be a good nurse—regardless of gender.

FOR INFORMATION CONTACT: Mike Goodkind (415) 497-6911 at Stanford University Medical Center or Vicki Applegate at Children's Hospital at Stanford 327-4800 ext. 363

The following release is being issued jointly by Stanford University Medical Center and Children's Hospital at Stanford.

HOSPITALS TO CONSOLIDATE PEDIATRIC FACILITIES

STANFORD—

The boards of directors of Stanford University Hospital (SUH) and Children's Hospital at Stanford (CH@S) have agreed in principle to consolidate the pediatric facilities of both institutions.

The agreement was accepted unanimously by the SUH Board of Hospital Directors Wednesday morning (July 21) after the CH@S board had voted agreement the night before.

Kenneth H. Sayre, chairman of the board of CH@S, and Dr. Lawrence G. Crowley, president of SUH, said details of a contract formally establishing the new hospital must still be completed with agreement expected within a few weeks.

The new hospital, which will retain the name Children's Hospital at Stanford, will be housed in a new facility to be built at an estimated cost of $40 million in conjunction with Stanford's Hospital Modernization Project, a $71.4 million construction project ($123.9 million including financing and other costs) expected to be completed in May 1987.

Physically attached to SUH, the new facility will consolidate the 60 beds of CH@S and the 44 pediatric acute medical-surgical and pediatric intensive care beds of SUH. The new facility will also house the Stanford-Children's Ambulatory Care Center, which provides 27 separate clinic services, including such specialties as cardiology, birth defects, oncology and child psychiatry.

The new children's medical center will continue to provide inpatient services in the 15 specialties now offered by both hospitals. These include such specialties as orthopedics, genetics, neurology, and neonatal intensive care.

Following the action of both boards, Sayre and Crowley issued a joint statement:

"We're confident that our action will lead to providing the highest quality and most efficient care for the children of the region. Equally important, it will also serve as a premier referral, teaching and research center for children everywhere.

"The effort is exciting because it centralizes under one roof the resources of two institutions which already share a great wealth of resources, skills and services."

-more-

2-2-2

The new CH@S will have its own corporate identity with a board of directors comprised of five members of the current CH@S board and five from SUH's board. The new CH5S board and the SUH board will participate jointly in raising the $40 million in project costs.

The present CH@S hospital would continue to be occupied until the new facility is ready for occupancy. Plans for the present building are not final, and an architect for the new building will be selected by the new board after a formal contract is ratified.

The new agreement in principle divides responsibility for providing various patient care and support services between SUH and CH@S. For example, inpatient pediatric services will be located in the new CH@S, while operating rooms, emergency services, normal newborn nurseries and radiation therapy will be provided by Stanford. The neonatal intensive care unit will continue to be located at SUH but will be managed by CH@S.

The new CH@S will have its own executive director, appointed by the new CH@S board, and a chief of staff appointed by the same board in consultation with the dean of the medical school.

CH@S, a nonprofit institution, and the Stanford University School of Medicine have maintained close ties since the pediatric institution was established at the campus in the 1920s. In recent years, Children's has been an affiliated teaching hospital of the medical school.

Both hospitals share a common medical staff whose members serve on the Stanford medical faculty, and Stanford interns, residents and medical students serve at CH@S.

Formal planning for development of a single children's medical center was begun by both boards in November 1981. A joint planning committee was established and a feasibility study was undertaken.

But informal consolidation discussions have been occurring for many years and have centered on rising costs, concerns about duplication of services, as well as trends in pediatric care, which resulted in attracting to Stanford the more difficult-to-treat cases.

Physically, the hospitals are now one mile apart and separated by a major throughfare. This has required the transportation back and forth of more than 2,500 patients yearly who must receive specialized services available only at SUH.

The consolidation must still pass through the review process of state and local agencies.

STANFORD—

Could diabetics better control their blood sugar through the use of both insulin and oral agent therapy?

Diabetic volunteers are needed to help answer this question by participating in research conducted by Dr. Gerald Reaven and associates at the Clinical Research Center at Stanford University Hospital.

To be eligible for this study, volunteers must have adult onset diabetes; be aged 20 to 69, male or female; be currently on insulin; and not be on oral agents.

Participants will be offered the following free of charge: evaluation of blood sugar, insulin and lipids (cholesterol and triglyceride); hospital and skilled dietitian-supervised weight reduction; routine health evaluation including liver and kidney function tests, cardiogram, chest X ray, physical exam, and dietary evaluation; and meals during the entire study period.

Anyone interested or wishing further information should call Dr. George Liu or Dr. Claude Lardinois, at 497-6054 between 9 a.m. and noon; or Ann Coulston, R.D., at 497-5430 between 1 and 5 p.m.

POTENTIAL MEDI-CAL, MEDICARE IMPACT STUDIED BY COMMITTEE

STANFORD—

The potential impact on Stanford University Medical Center of recent Medi-Cal changes will be studied by a special committee, Dr. Lawrence G. Crowley, vice president for medical affairs, announced Wednesday (July 14).

"In order to ensure a continuously improving level of patient care and teaching excellence at Stanford University Hospital (SUH) and the Stanford University Clinics, we need to examine very closely what impact, if any, will result from changes earlier this month in California's Medi-Cal legislation," Crowley said.

The committee will be chaired by David S.P. Hopkins, director of the Medical Center's office of analysis and planning and executive assistant to Crowley.

Hopkins said he hopes the committee will be able by Sept. 30 to summarize the potential effects of new laws and possible action which might be needed by the hospital and the clinics.

Included in the analysis, he said, will be potential effects of impending federal Medicare legislation, particularly proposed funding cutbacks and belt tightening moves.

Gov. Jerry Brown signed into law June 30 a Medi-Cal bill which potentially alters where both Medi-Cal and privately insured patients may seek medical attention.

Currently the Medi-Cal program is conducted on a fee-for-service basis, permitting recipients a free choice of providers or prepaid health plans.

The new bill authorizes the state Department of Health Services to negotiate contracts with hospitals, clinics or physicians. Patients would then be sent to a facility or physician with a state contract. Selection could be made on the basis of competitive bidding or negotiation, although other mechanisms could also be used.

"Fortunately the bill was amended just before passage to recognize that teaching hospitals, such as Stanford, provide specialized care for very sick patients or those with unusual maladies," Hopkins said.

-more-

"We are hopeful that the state will continue in fact to allow patients to be matched with the most appropriate health facility for their own needs while continuing to pay a fair share of patient costs," he added.

Related legislation also enables insurance companies to select via contracts specific hospitals, clinics or physicians to care for private policyholders. This would enable private insurance companies to tell their policyholders where to seek treatment.

Hopkins said the committee will be investigating whether cutbacks and restrictions about where treatment is delivered could tend to create a "two-tier" health system, requiring poorer patients to seek treatment in cheaper or publicly supported-hospitals, leaving the more expensive non-government supported hospitals for those wealthier patients who need not rely on Medi-Cal or insurance payments.

In the fiscal year which ended last Aug. 31, Medicare accounted for 25 percent and Medi-Cal represented 15 percent of the approximately 23,000 patients at SUH. During the same period, Medi-Cal constituted 13 percent and Medicare represented 12 percent of the approximately 50,000 patients at the out-patient clinics, which are operated separately from SUH and staffed with physicians from the Faculty Practice Plan who work closely with interns and residents.

Crowley added that he wanted the committee to study closely what impact the new legislation might have on the university's teaching programs.

"Both the hospital and the out-patient clinics depend on a diverse population of patients so that medical students and interns and residents may secure the experience they need to they complete their education. The effect of the new legislation is truly uncertain; that's why we need this study."

Other changes included in the California legislation more narrowly define the categories of persons who will be eligible to receive state medical assistance. For example, the bill reduces the maximum income of potential recipients and sets a lower limit for the amount of real property which a recipient may own and still be eligible for Medi-Cal.

Members of the committee, besides Hopkins, include Sheldon King, director of SUH; David Mendelow, associate dean for Medical School administration; Donald Tower, director of the Faculty Practice Plan; Dr. James F. Silverman, chief of staff for SUH; David Sakai, SUH director of finance; Dan Heath, associate director of finance for SUH; Dr. David Korn, chairman of the department of pathology; Roland Merchant, director of the SUH office of management and strategic planning; and David O'Brien, planner-analyst in the office of analysis and planning.

STANFORD—

Pilar Estassi came to California from Columbia when she was 18, intending to earn a nursing degree. This fall, 12 years later, she is going back to South America without a nursing degree, but with experiences and qualifications she considers to be of much greater value. A graduate of Stanford University Medical Center's physician assistant (PA) program, Estassi is going to Venezuela to assist in developing a similar program—an opportunity she doesn't think she would have been given without her preparation at Stanford.

PAs in the United States are trained to provide primary health care under physician's supervision in areas—primarily rural or inner-city—in which there is a shortage of physicians. In Venezuela, there are no PAs, and nurses are not as highly trained as in the U.S. either, Estassi says. She and three others will be working under the direction of Dr. Pablo Pulido, medical director of the Medical Center La Trinidad, in Caracas. With funds from the World Health Organization and the United Nations, Pulido's longterm goal is to set up a health care delivery system through which all South Americans will be able to obtain adequate primary care. He plans to do this by creating small centers throughout rural regions staffed by nurses trained in 'simplified diagnostic medicine,' which is similar to PAs' training, Estassi says. Her job is to help develop the curriculum for the Venezuelan program, and to help train the nurses as well.

"If I hadn't come to Stanford," Estassi notes,"I would've missed out on a lot of important experience." As a translator at Stanford Hospital for three years prior to entering the PA program, Estassi worked with many Latin American patients. Many had obviously been medically underserved their entire lives, she says.

"I saw how many of their problems could've been prevented with preventive health care and education," she continues. Realizing the needs of the patients and being exposed to various professions within the health care field helped Estassi decide to become a PA.

"I wanted to be more involved in decision-making than I thought I would have been as a nurse," she recalls. "And I didn't think I could afford medical school."

In order to qualify for Stanford's PA program—one of only five in the state—Estassi, like other applicants, had to be a U.S. citizen or have a permanent visa, had to have a high school diploma or equivalent, and six months experience in direct patient care. Estassi satisfied this requirement with her translator work at the hospital, in addition to work at Alviso's Women, Infants, and Children Clinic, geared towards helping women with high-risk pregnancies and high-risk infants.

The first year of the tuition-free program is spent doing coursework in subjects such as anatomy, physiology, and biology. The second year is almost entirely clinical.

-more-

2-2-2

Estassi and other students are required to find a preceptor—a physician who will sponsor them so they may complete the clinical requirements. It is during this year that they become skilled in taking patient histories and complete physical exams, performing and assisting in routine lab and screening procedures, routine therapeutic procedures, and various other duties that make up their scope of practice.

Following completion of the program, they must pass an exam administered by the National Commission on Certification of PAs for certification. They can then practice under the supervision of a sponsoring physician, as specified by their regulating body, the Board of Medical Quality Assurance, which is part of the state's Department of Consumer Affairs.

Estassi completed her clinical work at clinics in Alviso and at the hospital's emergency room. Her experiences, which primarily consisted of dealing with medically underserved minorities in pediatrics, obstetrics and gynecology, and nutrition, will help her out in Venezuela where she hopes to practice as a PA in addition to helping develop the program. She also forsees dealing with many tropical diseases, about which she is anxious to learn.

One of the major roles she sees for herself, both in Venezuela and in California, where she plans to return, is that of the patient educator.

In addition to the challenges patients will present during her Venezuelan stint, Estassi will face the challenge of being the first, and most likely the only, PA in Venezuela.

"In the U.S. there is some friction between physicians and PAs because some physicians resent having a PA, who has only gone to school for two years, want to diagnose and treat patients. You just have to understand your limitations as a PA, and prove yourself," she explains. "In Venezuela though, they have no idea what a PA is. I feel it's up to me to make a good impression for the whole profession."

And with her preparation at Stanford, Estassi is confident she has the ability to do just that.

FOR IMMEDIATE RELEASE

STANFORD—

Alumni and friends of Stanford University School of Medicine contributed $563,937 for medical scholarships from September 1980 to December 1981.

The contributions qualified the Medical School Alumni Association's Medical Fund for a $50,000 matching grant from the Henry J. Kaiser Family Foundation.

The gifts amounted to a 150 percent increase over the base years of 1978-79, said Harold Boyd, director of the Medical Fund. The total number of new donors increased 47 percent. Forty percent of those who gave during 1978-79 increased their gifts during the challenge period.

The challenge grants were offered to 13 private medical schools. They were accompanied by an outright gift of $100,000.

STANFORD—

Eleven assistant professors at the Stanford University School of Medicine were awarded research funds in June through the Biomedical Research Support Grant program, sponsored by the National Institutes of Health.

Award winners and their projects include:

Frank M. Torti, M.D., of the Department of Medicine, who is studying "Evaluation of Response or Progression in Metastatic Prostrate Cancer."

Mervyn Maze, M.D., of the Department of Anesthesia, who is studying "Adrenergic Function and Cardio-Pulmonary Bypass."

Brian Hoffman, M.D., of the Department of Medicine, who is studying "Monoclonal Antibodies to Adrenergic Receptors."

Walter Holder, M.D., of the Department of Surgery, who is researching "Isolation and Characterization of Human Breast Cancer Immune Complex Antigens."

Ron G. Rosenfeld, M.D., of the Department of Pediatrics, who is studying the "Interaction of Somatomedin with Receptors of Human Cell Lines."

Paul F. White, Ph.D., M.D., of the Department of Anesthesia, who is studying "Pharmacokinetics and Pharmacodynamics of Ketamine and Its Optical Isomers."

Vera Morhenn, M.D., of the Department of Dermatology, who is researching the "Inhibition of Human Keratinocyte Growth Using a Murine Monoclonal Antibody Directed Against Benign and Malignant Human Basal Cells of the Skin."

Thomas Okarma, Ph.D., M.D., of the Department of Medicine, who is studying the "Intervening Sequence Recognition by Small Nuclear Ribonucleoproteins: Characterization of snRNA-Associated Peptides."

Ann M. Arvin, M.D., of the Department of Pediatrics, who is researching an "Analysis of Immunoglobulins to Varicella Virus by Radioimmunoassay and by Immunoelectrophoresis."

John C. Giacomini, M.D., of the Department of Medicine, who is studying "Resolution of the Optical Isomers of Verapamil."

Paul T. Pitlick, M.D., of the Department of Pediatrics, who is researching the "Dose Response of Prostaglandin E1 in Newborn Piglets: Evaluation by Cardiac Catheterization and Digital Subtraction Angiography."

A faculty committee headed by Dr. Eric Shooter, professor and chairman of the Department of Neurobiology, awarded each researcher a $5,000 suballocation from the NIH grant.

The grant is designed to aid young scientists in initiating basic and clinical investigations, particularly in the areas of biomedical and behavioral research.

CORRECTION

In a release dated Aug. 5, 1982, entitled **GENETIC ENGINEERING PATENT DELAYED**, *The Stanford University Medical Center News Bureau erred by calling an "office action" issued by the U.S. Patent Office a delay in the patent. While Stanford officials believe that the patent ultimately will be issued, the press release should have called the action a tentative rejection, since technically that was the action taken by the Patent Office. We regret the misinterpretation.*
For publications which may still wish to consider offering their readers an account of the Patent Office's action, we offer the following clarified version:

Stanford University officials were told Wednesday, Aug. 4, why the U.S. Patent Office tentatively rejected claims in support of a genetic engineering patent sought by Stanford and the University of California.

The Patent Office issued an "office action" or decision on Monday, Aug. 2, which Niels Reimers, director of Stanford's office of technology licensing, received Wednesday.

News accounts had indicated in late June that the patent might be delayed, and while the office action constitutes an initial rejection, Reimers expressed confidence that the University's response will overcome the rejection. He said the university expects to file a response to the issues raised in the "office action" before a three-month deadline.

The patent application covers the products of basic gene splicing and cloning methods invented by Stanley N. Cohen, professor of genetics at Stanford, and Herbert W. Boyer, professor of biochemistry at the University of California at San Francisco (UCSF). An earlier patent covering basic techniques involved with the process had been issued in December, 1980.

"In its action this week, the Patent Office raises several questions which must be addressed before the patent can be issued, but none of the issues seem to be insurmountable problems," said Reimers.

"While not a patent attorney, I have reviewed the office action issued last Monday and anticipate that our patent attorney will be able to prepare a response that will allow the patent to be issued," Reimers said.

Normally the patent prosecution is confidential until the patent is issued. In this case Stanford chose to open up the process for public scrutiny to ensure that all potential objections might be raised.

Chief among the issues raised by the Patent Office is the question of whether or not the patent as filed was "enabling"—accurate and detailed enough to permit other researchers to use the genetic engineering techniques described.

-more-

The patent includes a description of how a particular plasmid (a circular form of DNA) formed during Cohen's and Boyer's original experiments. However, later experiments by Cohen showed that the interpretation detailed in the patent was incorrect.

Reimers said that the description was a tangential issue, since the basic genetic engineering process described in the patent has been proven to work in laboratories throughout the world.

A second issue is that a DNA process analogous to the one described in the patent can occur in nature under special circumstances. However, Reimers said scientists have pointed out that the naturally occurring process happens too infrequently to be useful for commercial gene cloning.

Third, the Patent Office noted that a 1980 news article in the British scientific journal *Nature* reported that Robert B. Helling, one of the collaborators on the original gene cloning experiments, had declined to sign a disclaimer of inventorship. He was a visiting scientist at UCSF at the time.

Reimers noted that Stanford's patent attorney has judged Cohen and Boyer to be the sole inventors, but the attorney has requested further information about Helling's role in the research and would be prepared to consider any evidence he might provide.

Reimers said the patent attorney representing Stanford, Bert Rowland, was expected to respond to the U.S. Patent Office well in advance of an early November deadline.

A first patent, which covers the basic techniques of gene cloning, was the first of its kind to be issued in the United States in 1980. The second patent—the subject of the current office action—was filed in 1974 and covers products resulting from the use of the technique. (These products, called transformants, are the result of intermediate steps between the genetic raw material and the desired commericial product).

Licenses are being granted by Stanford and UC to industry on a non-exclusive basis for reasonable royalties based on the gene cloning techniques, Reimers said.

Licenses issued so far to 73 firms have resulted in income to the universities of about $1.4 million, he added.

No products are commercially available now, Reimers said, but insulin, a human growth hormone, and a vaccine for scours (a disease of swine) are expected to be available by the end of the year.

In the case of the recombinant DNA method and product patents, both Cohen and Boyer have waived their right to personal royalties from payments accrued from licensing of the patents.

In addition to creating a powerful research tool for analyzing the complex workings of genes, the techniques make possible the construction of "bacterial factories" that can safely produce large quantities of compounds important in medical treatment.

Because bacteria theoretically could be engineered to produce almost anything created naturally by plant and animal cells, the techniques developed by Cohen and Boyer may have significant applications in industries as wide ranging as energy, chemicals and agriculture.

TWO STORIES: Lisa Ames (415) 497-6911

STANFORD—

"Infancy: New Research and Clinical Implications" is the theme of the second annual symposium on Advances in Developmental Knowledge to be held at the Stanford University School of Medicine Nov. 13 and 14, 1982.

Key-note speaker for the symposium will be Daniel Stern, M.D., from the Cornell Medical Center and the Columbia University Center for Psychoanalytic Training and Research.

Major presentations will be made by Thomas Anders, M.D., head of Stanford's division of child psychiatry, Anneliese Korner, Ph.D., research psychologist, and Isabel Paret, child analyst from Stanford's department of psychiatry.

To be held in the Fairchild Auditorium at Stanford, the symposium will consider the research and clinical aspects of biological and psychological development in early infancy. Scientific papers and discussions will address both normal development and the possible pathologies arising from this period. Small discussion groups will be held as part of the program.

Included among the participants will be Jeree Pawl, Ph.D., from the Frailberg Project at San Francisco General Hospital, and child analysts Joseph Afterman, M.D., Philip Spielman, M.D., and Calvin Settlage, M.D. Professor Colin Pittendrigh of the Hopkins Marine Station, an authority on biological rhythms, will also be present.

The symposium is sponsored by Stanford's division of child psychiatry, Children's Hospital at Stanford, and the extension division of the San Francisco Psychoanalytic Institute. It is intended for researchers, clinicians, mental health professionals, nurses, pediatricians and academicians interested in human development.

Early enrollment is recommended. The registration fees will include a box lunch and reception Saturday afternoon. For program and registration information, call (415) 563-5815.

STANFORD— —30—

What is the impact of diet on aging? What are the effects of age on dietary requirements?

Research volunteers are needed to help answer these questions, by participating in short-term studies in nutrition and metabolism conducted by Dr. Robert Marcus and associates at the Aging Study Unit, Veteran's Administration Medical Center, Palo Alto.

In order to participate in these studies, volunteers must be over 20 years old and be in good health. Participants will be offered free of charge a comprehensive health screening examination, including history and physical examination, blood pressure and glaucoma checks, chest X-ray and electrocardiogram, and complete blood count. Volunteers will be admitted overnight to the Aging Study Unit, where dietary evaluation and meals will be provided during the entire study period.

Anyone interested in participating in a study, or in obtaining additional information about the program, should call Pam Wooldridge between 8:30 a.m. and 4 p.m. weekdays, at (415)493-5000, extension 4572.

RISING PRICETAG ON ENERGY URGES REDUCED USE

Editors: Graphic summary of current avoided costs available if not included

STANFORD—

In the face of high energy costs certain to escalate dramatically within a year, the Medical Center has stepped up measures to reduce both energy usage and expenditures.

According to conservation coordinator Sean Mooney, activities have centered around the modifications of building systems, new projects, and long-term planning—with future guidance from the committee on energy resources.

But budgeting for energy consumption poses other challenges, since it necessarily reflects changing policies and numerous factors outside the Medical Center's control. Over the last few months the economics surrounding local and national energy matters have proved erratic.

"That's why it's crucial for us to move forward agressively with our own conservation efforts before the inevitable price rises hit," said Mooney, "and to monitor external developments closely."

The City of Palo Alto, Mooney explained, is the Medical Center's major electric utility supplier, furnishing approximately 26.4 million kilowatt hours (KWH) per year. At present rates this amounts to $715,800 for 1981-82.

The city purchases most of its power from the federal government. Last spring it was announced that because of a federal rate adjustment, there would be an increase in commercial user rates of approximately 80 to 90 percent by May of 1983.

Combined with a July 1, 1982, rate increase of approximately seven percent and based on the Medical Center's consumption, said Mooney, this would increase the cost of electricity in 1982-83 to at least $995,000.

Meanwhile, the Medical Center's total gas expenditure for 1982-83 is expected to be approximately $1.6 million. Proposals to accelerate decontrol of natural gas could increase costs by 1985, without inflation, by between 60 and 95 percent.

If consumption rates are held approximately constant, this would mean a 1985 gas bill of $2.6 to $3.2 million, said Mooney.

"Obviously, the energy situation at the Medical Center right now demands both our attention and our action."

He stressed, "There is hope for saving energy if everyone who works here pitches in." Posters encouraging conservation have been placed throughout the Medical Center, and an outdoor display on the Center's efforts is in the works.

A new Energy Information Service is available with conservation tips for office and home; members of the Medical Center community have been encouraged to call with questions and ideas.

Already, said Mooney, measurable progress has been made. The Medical Center experienced a 2.9 percent overall reduction in energy use in 1980-81, compared to base year 1979-80. The projected decrease over the base year for 1981-82 is 4.9 percent.

-more-

2-2-2

Currently, the Facilities Department's premier project involves tackling a heating problem the Medical Center has had since it was built, said Mooney. Modification of the heating system will first take place in the Edwards Building, with all other similarly heated buildings to follow.

"The existing system was built in such a way that the whole building comprises one heating zone, with no occupant control of heating levels. This has caused discomfort as well as major energy waste over the years," he explained.

The project, which Mooney said he hoped to see accomplished over the summer, will divide the building into twelve zones, each of whose occupants will be able to regulate their heating. Total project cost is estimated at $35,000 to $45,000. Steam savings are estimated at $29,000 per year, at 1982-83 rates.

Another major project is to upgrade the flood lighting around the Medical Center's perimeter. The present lighting consists of 18 incandescent fixtures of 1,500 watts each, Mooney explained. "The fixtures are quite old and in varying states of disrepair, causing constant relamping and maintenance problems."

If the existing fixtures are replaced with fifteen 400 watt high pressure sodium units, he said, light output will increase by 40 percent per fixture while electrical usage will be reduced by 74 percent.

"We'll avoid spending $6,000 per year for operation and maintenance," said Mooney, "at present cost levels." The project cost is estimated at $8,500.

Yet another conservation effort involves removing one-half the lamps or introducing special energy saving devices in appropriate fixtures throughout the Hospital's main public corridors.

"The existing fixtures were installed at the time of initial construction and have deteriorated due to accumulation of dirt and discoloration," said Mooney.

Their present total electrical usage is 367,000 KWH per year. Savings resulting from the project will be 166,000 KWH per year, with total operational and maintenance avoided costs of $13,200 at present rates. The project cost is estimated at $30,000.

Mooney is hopeful that other similarly optimistic projects will be undertaken at the Medical Center.

"With more internal metering and expanded analysis, we will be better able to define usage patterns and also refine our budgeting process," he said.

Hoping for greater control of escalating utility rates, Stanford's Energy Program Office recently hosted a meeting to plan an Energy Consortium of colleges, universities, and hospitals throughout California.

"This will enable us to have a direct impact on the rate-making process, something we don't presently have as institutions and major energy users," said Mooney, adding that the Medical Center lends this University-wide effort its full support.

PALO ALTO CITY COUNCIL ADOPTS RESOLUTION SUPPORTING HMP

STANFORD—

The Palo Alto City Council approved unanimously Monday night (Aug. 9) a resolution supporting Stanford University Hospital's Modernization Project.

The council also told Stanford that it reserved the right to rescind its endorsement in 90 days if a hospital-based committee had not made what council members deemed sufficient progress toward settling longstanding discussions about physician access to hospital-based services.

The council's endorsement for the $124 million project was sought by SUH as it files for a certificate of need (CON) from public agencies. The council endorsement is not required. However, the state and regional agencies which issue the CON, review local community support while assessing whether the requested improvements are needed in the local area.

The resolution sought by Stanford and approved Monday night was an endorsement offering support for the project in principle. The resolution specifically noted that the support "does not constitute advance approval by the City of Palo Alto of any of the financial, environmental or physical aspects of the modernization project. The action of the City on those aspects within its regulatory authority must await full public hearings and review in accordance with the City's adopted procedures."

Mayor Fred Eyerly noted that Stanford has told him that it plans to seek state—and not city—backing for the $80 million portion of the project Stanford plans to finance with revenue bonds.

The resolution was first presented to the council July 27, and since then has served as the focal point of a debate about access by community physicians to hospital-based services.

For many months, SUH and local physicians have been negotiating the rules for community physicians' use of certain hospital-operated medical services, such as clinical labs, cardiac catheterization, radiology and the hemodialysis center.

At the most recent council session, Councilmember Emily Renzel said that she would monitor closely the access issue during the 90-day period.

"I will look very closely . . . . (Access to beds by patients) is meaningless if our citizens do not have a meaningful choice of health care."

She referred to whether patients will be able to choose their own community doctor to perform services.

She said that while she supported the HMP, the issue of access must be "at some point resolved to our satisfaction."

-more-

Councilmember Larry Klein, said the council's interest in the access question centers on whether alo Alto residents are provided with the care they desire "not with whether a certain group of doctors have an opportunity to go in and make a lot of money."

Sheldon King, director of SUH, has said that no major hospital can operate without providing restrictions on which physicians have access to labs operated by the facility.

The 90-day period set forth by the council was timed to provide the access committee, which consists of Stanford physicians, local doctors, and lay community members, an opportunity to smooth over differences about the principles on which access is based.

Since final action by the HSA is not feasible within 90 days, the time frame could give the council time to withdraw its support.

However, the resolution sent to public agencies Monday makes no reference to conditional support or the council's intention to review the matter in coming months. These issues were handled in two separate actions passed Monday.

Stanford and Palo Alto's discussions about hospital matters began prior to 1959, when Stanford University Medical Center moved to Palo Alto from San Francisco, and the university began operating a hospital jointly with the city. In 1968, Stanford bought out Palo Alto's interest in the hospital and entered a 10-year contract to provide community hospital services to the city, including reserving 370 beds for community physicians.

"You all know," Stanford President Donald Kennedy told the council, "that the Stanford Hospital operates under a set of access arrangements that is unique in academic medicine. They derive directly from the nature of the arrangements under which the hospital was built."

In asking support, Kennedy said, "there is nothing that this council can do that will be more influential in improving the conditions of medical care for the community, or that will more dramatically improve the conditions of medical practice, including access to facilities, than to lend its wholehearted support to the HMP."

The HMP will provide about 325,000 square feet of new space at the Main Center and will renovate about 165,000 square feet of existing space. It will provide some 190 new replacement beds, including new critical care bed units. Also planned is a new 22-room operating suite.

The plan is essentially not an expansion of the hospital, and will add only six beds to the current licensed total of 663.

SEVERE ACNE ALLEVIATED BY NEWLY APPROVED DRUG

STANFORD—

Oozing, bean-sized abscesses that covered his face and neck made it difficult for David Smith (not his real name) to make friends, stay in school or even hold down a job.

"It became very hard not to have a desolate life," said Smith, 22, who for six years suffered from cystic acne, a severe form of scarring acne that resists traditional treatment and blights the skin of 350,000 young people worldwide.

Today Smith's face is clear, after a several-month treatment at Stanford with daily oral doses of Acutane (13-cis retinoic acid), a drug approved by the Food and Drug Administration last spring and slated to be available by prescription to the general public in mid-September. Eugene Farber, chairman of Stanford's department of dermatology, has directed one of several research teams appointed to evaluate the effects of Acutane in clinical trials.

"There never has been a drug that was as effective for severe acne," Farber said in an interview. "Acutane has been dramatic in almost everyone who has taken it."

The drug is one of a family of chemicals called retinoids that are derived from vitamin A and have been investigated for six or seven years for their ameliorative effects in various skin diseases and cancer. Acutane, manufactured by Hoffmann-La Roche, Inc., is the first of the group to gain FDA approval for acne treatment.

The drug's mode of action in the body is not completely understood, Farber said, although most research indicates that acutane shrinks the oil secreting glands that tend to be large and overactive on the face, back and chest of cystic acne sufferers.

Though a major boon to those with cystic acne, Farber cautioned, the drug carries with it a number of side effects that preclude its use in the mild acne associated with puberty and nervous tension."Cosmetic acne" responds well to milder, traditional treatments, he said.

Chapped lips, dry nose and throat, and peeling palms are typical side effects of Acutane treatment. Because the drug temporarily raises the blood levels of triglycerides (fatty acids implicated in heart disorders), persons with heart disease should not take Acutane, Farber said.

Retinoids have been associated with birth defects in animals, and remain biologically active for several months after the last dose, he added, so women considering pregnancy within six months after acne treatments end also should avoid the drug.

AUTISM FOCUS OF $150,000 AWARD

FOR IMMEDIATE RELEASE

STANFORD—

Hints that autism might be related to an overabundance of a chemical messenger in the brain soon will be tested by Roland Ciaranello at Stanford, under a three-year $150,000 award from the John Merck fund.

Ciaranello, 39, an associate professor of psychiatry, is one of the first two recipients of a "John Merck Research Fellowship."

Ciaranello said he will use the grant to expand an ongoing study of the biochemical roots of autism, an illness that strikes one of every 2,000 children, and is often marked by debilitating social and emotional withdrawal, and severe language disability.

Research of the last decade has indicated that up to 40 percent of autistic children may have abnormally high blood levels of serotonin, a chemical messenger between nerve cells in the brain.

No one yet understands the significance of elevated serotonin levels, or how levels measured in the blood are related to levels in the central nervous system, Ciaranello said.

However, a preliminary study from University of California, Los Angeles researchers, published in the July 15 *New England Journal of Medicine*, reported that three autistic children treated with fenfluramine, a drug that temporarily reduces brain serotonin levels in animals, showed a reduction in both the behavioral symptoms of their disease and levels of serotonin in their blood.

The UCLA study provides yet another clue that the disease is biological rather than psychological in origin, said Ciaranello, though mechanisms of the disorder are far from understood. While it is important to dispel the myth that autism is caused by cold, neglectful parenting, further exploration of the biological changes associated with the disease is crucial, he said.

-more-

"It is premature to congratulate ourselves on our enlightenment simply because we no longer blame parents," Ciaranello wrote in an editorial also published in the July 15 *Journal*. "Without biologic markers, diagnosis remains heavily dependent on behavioral criteria. Yet early diagnosis, even as early as infancy, may be critical in the successful implementation of language and educational programs."

Since 1979, a team of researchers led by Ciaranello and Thomas Anders, professor of psychiatry, has been collecting biochemical and behavioral information from 106 autistic children in the bay area but has lacked funds to complete a detailed analysis of the information.

The Merck fund grant will enable the scientists to increase the size of the group studied, Ciaranello said, and to compare the behavioral patterns and levels of serotonin and its byproducts in three groups of children: those with autism, those who are mentally retarded but not autistic, and normal children.

In a separate study, levels of endorphins, another set of brain chemicals implicated in pain perception and in several mental disorders, will be measured, he said, to test the theory that autustic children have a diminished response to pain.

"Since endorphin and serotonin-containing nerves interact, there is a possibility that the two studies will yield very interesting data," he said.

A 1970 graduate of Stanford University Medical School, Ciaranello received his undergraduate degree from Union College in New York. He has been a member of the Stanford faculty since 1978 and previously was a research associate at the National Institute of Mental Health in Maryland.

Initiated in 1982, the Merck fellowship funds "promising young professionals" who are studying the problems of "doubly disabled children"—those with both mental and emotional disorders—said a Fund spokesman. James Leckman, a child psychiatrist at Yale University, is the other 1982 Merck Fellow.

Serena S. Merck, wife of the late George W. Merck, former president and chairman of the board of Merck and Co. Inc., established the Fund in 1982 to honor their son, John.

HOSPITAL RECEIVES THREE-YEAR ACCREDITATION

STANFORD—

Stanford University Hospital has become one of the first university teaching hospitals in the nation to receive three-year accreditation from the Joint Commission on the Accreditation of Hospitals.

In an accreditation letter received Aug. 3 by Sheldon King, executive vice president and director of SUH, the commission said the Hospital "is to be commended for its efforts in providing high quality patient care."

However, the commission noted an excessive number of delinquent medical records, and told Stanford its accreditation "was contingent upon quarterly written progress to be submitted for a period of 12 months."

Four months before the survey, the number of incomplete patient charts had reached nearly 4,000.

The number was reduced to less than 600 at the time of the survey team's March 15-17 visit. Stricter procedures, including disciplinary measures, were instituted to ensure that physicians, including housestaff, would finish their records in a timely fashion and continue to reduce delinquent records to manageable levels, said Mary Catherine Krawec, the associate hospital director responsible for JCAH preparations.

"What is most significant," said King, "is that our survey showed the level of care at the Hospital to be consistently excellent. The survey results stem not only from the effort expended to prepare for the survey, but more importantly, from the continuous day-to-day work by employees and medical staff.

"The notice we received about medical records should be a clear message that we cannot reduce our efforts or neglect any aspect of our hospital operation.

"We will be watched very closely during the next 12 months and throughout our three-year accreditation. If we view this as a lesson to sober us, not a burden to avoid, we will head into the next inspection with greater strength."

-more-

Krawec emphasized that the problems with the medical records involved no threat to safe patient care. The omissions included such technical matters as missing physician signatures or routine record-keeping data.

The JCAH inspection was conducted as part of a Consolidated Accreditation and Licensure Survey, which also included inspection teams from the state Department of Health Services and the California Medical Association. SUH's California license was renewed in early June.

Krawec said JCAH accreditation ensures that SUH is linked philosophically to the top hospitals in the country and serves as an endorsement in attracting personnel, including housestaff and faculty.

The accreditation requires that Stanford conduct its own survey in 18 months, mid-way through the three-year accreditation. Previously JCAH granted one and two-year accreditations, requiring more frequent on-site visits by JCAH physician-inspectors.

Now that the current inspection has been completed, Krawec said she is pleased but doesn't plan to disband the approximately 35-member committee which worked to prepare for the survey.

"In years past a different procedure was used. Administrators would each take responsibility for a particular aspect of preparation for the inspection," Krawec said.

But this year, several months before the inspection, Krawec said she met with a group of department heads from units where preparations were most critical.

"And this group expanded quickly to about 35 people representing every area of the hospital, who worked together to evaluate what needed to be done, and then they went back and worked with their own people to implement it" in time for the inspection.

"This approach really made the preparations a team effort, and by keeping the team intact, we'll be able to keep things in order so that preparations for the next inspection in 1985 will be a continual, orderly affair."

SUH APPROVES 1982-83 BUDGET AND ROOM RATE INCREASE

STANFORD—

The Board of Hospital Directors of Stanford University Hospital (SUH) approved Wednesday (Aug. 18) a 1982-83 net operating budget of $161.9 million and a capital improvements budget of $7.2 million.

Also approved was a 13 percent average increase in the price of rooms effective Sept. 1.

The capital improvements budget included $1 million for a computerized admission, transfer and discharge system, which is expected to signficantly speed-up and streamline the processing of patient data. The capital budget also contained some $1.5 million for a computerized tomographic scanner and a linear accelerator to permit the hospital to incorporate the most advanced diagnostic and treatment techniques in the field of radiology, said Sheldon King, executive vice president and director of SUH.

When the fiscal year ends Aug. 31, the hospital is expected to have gross revenues totaling $192 million, an 8.1 percent increase over the $177 million predicted at this time last year.

The rising revenue, King said, resulted from approximately a 1.5 percent larger-than-expected patient population. In addition, King said, patients were on the average more acutely ill than predicted, and therefore needed more costly services.

In the 1982-83 fiscal year, the hospital is projecting total revenues of $226,982.

In addition to room prices, the board also approved a variety of price increases for various services, including an 11.6 percent rise for the operating room and 17 percent for use of the delivery room.

A typical room rate increase would be from $272 to $308 for a medical or surgical ward bed without intern or resident service.

Similar patients on the teaching service—those receiving the support of interns and residents—will pay $22 more.

Thirty-seven different rates, depending on the type and acuity of care, currently are in effect at SUH. These range from $205 per day for healthy newborn babies, to a maximum of $1,825 for the highest level of intensive and coronary care.

SUH last raised room rates May 15 an average of 5.9 percent.

Also contributing significantly to higher rates, King said, were shrinking revenues from Medi-Cal and Medicare, whose funding accounts for about half of the 25,000 patients cared for annually at Stanford.

-more-

He said that the difference between costs to the hospital and the amount of reimbursement made by Medicare and Medi-Cal will represent a $14.6 million loss to the hospital unless the non-public health patients and insurance providers make up some of the difference as they have in the past two years.

King noted that pending legislation could alter radically the way in which state Medi-Cal and federal Medicare services are dispensed, leaving the hospital's financial projections for future years uncertain.

And Donald Kennedy, president of Stanford University and chairman of the hospital board, cautioned "that predictions can only be based on what has already happened to our cost. Issues, such as the future directions of Medi-Cal or funding are too uncertain for reliable indicators of the future."

The increased prices, said King, were intended to compensate for inflation—including rising labor costs.

Less than 1 percent of the room increase would be used to help finance Stanford's Hospital Modernization Project, the improvement project expected to bring the hospital up to modern standards needed in coming decades, the director said.

King said that rising costs in a hospital environment are less controllable than in less critical environments.

"Obviously," he said, "we are doing all we can through careful management to reduce the impact of inflation and other costs. But this is extremely difficult in a high technology world where complex new technology and discoveries can't be ignored or delayed."

In another matter, the board made permanent its temporary committee seeking to answer questions of access by community physicians to hospital services.

Dean Morton, a community hospital board member who serves as chairman of the Board Access Committee, said the group is making progress and fully expects to meet a 90-day time frame requested by the Palo Alto City Council.

The city on Aug. 9 unanimously adopted a resolution supporting the HMP, but said it reserved the right to rescind its endorsement in 90 days if the committee had not made notable progress toward settling the longstanding access dispute.

An endorsement of the project from Palo Alto is not required, but Stanford had sought the action because support by state and regional agencies which must approve the project review community support while assesing whether requested hospital improvements are needed.

The new committee, which is responsible for monitoring the implementation of the hospital's physician access policy, includes both community and fulltime Stanford faculty physicians.

Kennedy said he would draft and send a joint letter with Lawrence G. Crowley, vice president for medical affairs, informing the City Council of the new standing committee and its charge.

DRUG GIVEN TWO WAYS TO ABORT HEART ATTACKS

STANFORD—

Two methods for administering streptokinase, a drug newly used for treating heart attacks in progress, are being compared for effectiveness at Stanford University Hospital.

When given via the intracoronary route, streptokinase is infused directly into a blocked artery, explained Dr. Edwin Alderman, director of the Catheterization-Angiography Laboratory. Alternatively, the drug may be given intravenously, which is the method Stanford is testing.

The study is important, said Alderman, because thousands of hospitals do not have instant access to the cardiac X-ray filming equipment which the standardly used intracoronary route requires.

"Intracoronary infusion requires first performing catheterization and other tests on the patient, in order to determine exactly where the blood clot causing the heart attack is located," said Alderman. (In cardiac catheterization, dye or radio-opaque contrast substance is injected into the coronary arteries and movie pictures recorded.)

"If established as equally effective, the intravenous method would be much simpler and also faster. It could save 30 minutes to an hour in treatment time," he said.

Alderman is an associate professor of medicine in the Cardiology Division. His colleague in the study is Dr. Michael Eliastam, director of Stanford's emergency services department and assistant professor of medicine and surgery.

"Our impression so far, after treating 12 patients randomly one way or the other, is that the intravenous route is just as beneficial as the more complex, direct intracoronary route," said Alderman, cautioning that their data have yet to become statistically significant.

Streptokinase is an enzyme which activates the body's own blood-clot fighting mechanisms, to actually interrupt an attack and reduce the extent of irreversible heart muscle damage.

A heart attack, Alderman explained, in 85 percent of cases is precipitated by blood clot formation (or "thrombosis") in a coronary artery, at the site of a severe narrowing. The resulting attack is called an "acute myocardial infarction."

Alderman noted, "The initial process is a build-up of fatty material inside the wall of the artery, which leads to the narrowing."

Particularly if the narrowing becomes ulcerated and irregular, he said, it paves the way for thrombosis by the body's natural clotting mechanism.

The clot then obstructs blood flow, causing the heart muscle which had been supplied by the artery to die within hours, said Alderman.

Myocardial infarctions, he explained, have traditionally been handled from the standpoint of complication-free recovery rather than interruption, and post-attack care has been stressed.

"But initial investigations in the U.S. and Germany recently indicated that streptokinase infused promptly into a blocked coronary artery can result in thrombolysis (clot dissolution) in 85 percent of infarction cases," Alderman said.

-more-

He, Eliastam, and other faculty members have been collecting their own data since April. Many related studies worldwide are under way or being planned, Alderman noted.

A protein which comes from the bacteria streptococcus, streptokinase has been in use for several years to dissolve blood clots in pulmonary arteries and elsewhere in the body, said Alderman. It was only about a month ago, however, that the Food and Drug Administration approved the drug for intracoronary use in the treatment of acute infarction.

"With streptokinase therapy, time is of the essence," Alderman said, explaining that a heart attack patient must receive emergency evaluation within three hours after the onset of severe symptoms in order to maximize myocardial salvage.

Stanford's emergency department, he said, is prepared to provide streptokinase therapy at all times.

Alderman stressed, "Doctors should remind patients with known chronic anginal symptoms to contact them and report to the Emergency Department immediately whenever they suffer severe symptoms unresponsive to their usual medications."

Clinical reasons for excluding patients from streptokinase therapy include cardiac-originated shock, significant kidney or liver impairment, age greater than 75, or a severe life-limiting medical condition.

If the qualifications are met, and both the patient and attending physician consent to attempted thrombolysis, the necessary testing is carried out and streptokinase administered. Afterwards, the patient is admitted to the Hospital's coronary care unit.

Just prior to discharge, patients are asked to undergo further tests in order to help assess the extent of myocardial preservation.

"Using streptokinase is basically a matter of buying time," said Alderman. "Once you've aborted the heart attack you can go on to deal with the underlying arterial narrowings, plan further patient management, and hopefully prevent any recurrent attacks."

EXERCISE VOLUNTEERS SOUGHT FOR HEART DISEASE STUDY

STANFORD—

A team of Stanford University investigators will attempt to learn whether a drug taken by millions of heart disease sufferers will interfere with their ability to get in shape via exercise.

Some preliminary experiments with rats have indicated that beta blockers, drugs given to lower blood pressure and oxygen use by the heart muscle, might impede the cardiovascular system's ability to become healthier through exercise, said Mike Savin, a research associate in the Division of Cardiology.

On the other hand, at least one study has indicated that the drugs might actually enhance their takers' ability to improve cardiovascular fitness, while still other work suggests that the drugs have no affect on fitness.

Beta blockers, sold under such names as atenolol and propranolol, are the most widely prescribed category of cardiovascular drugs, and account for about $370 million in sales annually in the nited States, said Savin. They lower blood pressure and heart rate by attaching themselves to receptors at nerve endings in the body. The beta blockers serve as barriers to halt incoming chemical messengers which otherwise would tell the heart to speed up.

Elaine Gordon, a postdoctoral research fellow in cardiology, said it is possible that the interaction between the chemical messengers and the receptors—which does not occur while people take beta blockers—may be the stimulus causing improved fitness.

However, because of the inconclusive and sometimes contradictory data, Gordon said Stanford Heart Disease Prevention Program researchers are looking for 45 healthy but sedentary men between 20 and about 40 years old who will volunteer to take beta blockers while simultaneously starting an exercise program.

The volunteers will be divided into three groups. Fifteen volunteers will be given a beta blocker which works almost exclusively on the nerve endings in the heart (atenolol). A second group of 15 will receive beta blockers which are more general (propranolol) and will affect nerve endings in the heart as well as other parts of the body, Savin said. A third group will be given a placebo.

Potential volunteers must be in excellent health but should not have been involved in a physical fitness program for at least the past eight months, Savin said.

"We need to ensure that people are healthy enough to begin a vigorous exercise program, but we need people who are not in top shape so that they have margin to show measurable improvement."

-more-

All of the volunteers will be placed on a six-week personalized exercise program, consisting primarily of stationary bicycle riding. Progress will be carefully and continually monitored by researchers in a Stanford gym, the researchers said. Participants are expected to exercise for about 40 minutes, five or six times each week.

Neither the researchers nor the volunteers will know who is receiving drugs or the placebo, Gordon said. Volunteers will be given increasingly larger doses until their heart rate is lowered.

"At the end of the study, participants will receive extensive medical and fitness testing, and we will then compare if the placebo group showed more improvement than the volunteers taking beta blockers," Gordon added.

If the results show that healthy volunteers taking beta blockers fail to get in shape, "we will need to run further studies to learn if people who need beta blockers for therapeutic reasons are affected in the same way," Savin said.

The researcher said that the beta blockers pose no significant risks to healthy volunteers, although participants may experience some minor discomfort. Among anticipated side effects, he said, is possible dizziness and lethargy, since their blood pressure could be lowered below normal levels. "These effects, if they occur, can be stopped immediately when the drug is discontinued," Savin said.

Gordon said persons who regularly operate machinery would be eliminated as volunteers, since they would be prone to some risk. Also to be eliminated are persons suffering from asthma or diabetes, since their ailment could be aggravated by the drug, she said.

Potential benefits to volunteers "include the very strong possibility that they will be able to get in good physical shape. We are offering an extensive, well organized exercise program."

"If we find that volunteers in the group receiving beta blockers have failed to make physical improvements, we will work with them after the study to begin a personalized program off the drugs," Savin said.

Subjects will be paid $200 for the duration of the study, including $25 after the initial physical screening and a pre-exercise physical fitness test. The remaining $175 is to be paid after the test is completed.

Potential applicants are invited to call Savin or Gordon at (415) 497-6461 for further information or to enquire about an orientation meeting to be scheduled before the end of August at Stanford Medical Center.

The experiment has been approved by Stanford's Medical Committee for the use of Human Subjects in Research.

Researchers, in addition to Savin and Gordon, include William Haskell, clinical associate professor of family, community and preventive medicine.

CONSOLIDATION AGREEMENT SIGNED BY HOSPITALS

STANFORD—

The articles of incorporation for a consolidated pediatric medical facility have been approved by the boards of directors of Stanford University Hospital (SUH) and Children's Hospital at Stanford (CHS).

"We look forward to creating something truly superior," said Kenneth H. Sayre, chairman of the board of CHS. His board unanimously approved the formal agreement at a meeting Monday night (Aug. 23). The SUH board acted unanimously Aug. 18.

In July, both boards had formally approved the consolidation in principle.

The most recent action provides a formal corporate framework for the new $40 million pediatric hospital to be built in conjunction with Stanford's $71.4 million Hospital Modernization Project.

The pediatric facility, which will retain the name Children's Hospital at Stanford, will be physically attached to SUH and is expected to be completed in 1987.

Lawrence G. Crowley, vice president for medical affairs at Stanford, said, "With the consolidation, the close working relationship of our two institutions will grow even stonger, allowing our health professionals to provide increasingly excellent research and teaching facilities. Certainly children in our region will be the major beneficiaries of this move. But the impact of this new institution will surely be felt nationally."

The new CHS will have its own corporate identity with a board of directors comprised of five members of the current CHS board and five from SUH's board.

The medical center will consolidate the 60 beds at CHS and the 44 pediatric beds at SUH. New CHS will continue to provide inpatient services in the 15 specialties now offered by both hospitals and will house the Stanford-Children's Ambulatory Care Center, providing 27 separate clinic services.

CHS, a nonprofit institution, and the Stanford University School of Medicine have maintained close ties since the pediatric institution was established at the campus in the 1920s. Formal planning for development of a single children's medical center was begun by both boards in November 1981.

Currently the hospitals are one mile apart and separated by a major thoroughfare.

The consolidation must still pass through the review process of state and local agencies. The articles of incorporation must also be ratified by the trustees of Stanford University, when they meet Sept. 13 and 14 and hold a session as general members of the hospital.

JARDETZKY NAMED TO HEAD NEW DIVISION

STANFORD—

Oleg Jardetzky, director of Stanford's Magnetic Resonance Laboratory, has been named chairman of the board of a new division of biology and medicine of the International Society of Magnetic Resonance(ISMAR).

Formation of the new group was prompted by burgeoning uses for magnetic resonance as a diagnostic and exploratory tool in the life sciences, an ISMAR spokesman said.

First discovered in 1945 by Felix Bloch, a Stanford physicist, and E.M. Purcell of Harvard, nuclear magnetic resonance, or NMR, describes the tendency for the electrically charged cores of atoms to vibrate when placed in a strong magnetic field.

The phenomenon found its first use in physics and chemistry, where it permitted scientists to finely tune their views of the structure and behavior of complex molecules.

Since 1956, Jardetzky has pioneered efforts to turn the technique towards living cells, in hopes of establishing a molecular meter of the metabolic status, or healthiness, of organs such as the blood, kidney, or brain.

The International Society of Magnetic Resonance was founded in 1967 to promote applications of magnetic resonance in physics, chemistry, biology and medicine, and draws members from more than 50 countries.

"The establishment of the new division (of biology and medicine) is especially timely," Jardetzky said, "in view of the major contributions which NMR is making to the study of molecular biology, to the non-invasive investigations of biochemical pathways and control mechanisms in vivo, and, more recently, to the diagnosis of metabolic diseases. The task of the division will be to coordinate information and promote further advances in all of these areas."

-more-

A $660,000 nuclear magnetic resonance spectrometer, to be installed at Stanford in the fall of 1983, will bring to the United States the most powerful instrument of its kind. Financed by the National Institutes of Health (NIH), the spectrometer will be based on a persistant (stable) superconducting magnet with a strength of 14 Tesla—twice the strength of the spectrometer used now.

"The 600 megaherz spectrometer will provide to the scientific community at Stanford the most powerful instrument of its kind," Jardetzky said.

The 11-member board of directors of the new ISMAR division represents the full range of biological and medical applications of NMR, Jardetzky said, and is composed of individuals who have played a key role in their development.

The members of the board are: E.R. Andrew,FRSE (Physics, Nottingham, England), Mildred Cohn (Biochemistry,University of Pennsylvania), R.R. Ernst (Chemical Physics, Eidgenoessische Technische Hochschule, Zurich, Switzerland), J.J. Fischer (Radiology, Yale University), Sture Forsen (Biochemistry, Lund, Sweden), W.D. Phillips, (Chemistry, Washington University, St. Louis), A. Redfield (Physics and Biochemistry, Brandeis University), Sir Rex Richards, FRS (Biochemistry and Physical Chemistry, Merton College, Oxford University, England), Gordon Roberts (Biochemistry and Pharmacology, National Institute for Medical Research, London, England) and Kurt Wuthrich (Biophysics, Eidgenoessische Technische Hochschule, Zurich, Switzerland).

NEWS CONFERENCE TO HIGHLIGHT INTERNATIONAL NMR MEETING

Science writers: If you plan to attend the news briefing on nuclear magnetic resonance, please phone the News Bureau (415) 497-6911. Copies of the program are available on request if not included with the story.

STANFORD—

Chemists, physicists, biologists and physicians from 19 countries will meet at Stanford University Aug. 29—Sept. 3 for the Tenth International Conference on Magnetic Resonance in Biological Systems.

A news briefing by a panel of scientists to highlight the potential uses of nuclear magnetic resonance (NMR) in medicine is scheduled at 10 a.m. Friday, September 3. The briefing will be held in room TE 110, Psychiatry and Behavioral Sciences Building.

Oleg Jardetzky, director of Stanford's magnetic resonance laboratory, will lead the briefing which will precede an afternoon-long symposium for medical professionals in Fairchild auditorium on the clinical uses of NMR.

More than 300 lectures, symposia, and poster sessions during the six-day meeting will focus on NMR, the tendency for the core of an atom to vibrate in predictable ways when subjected to a strong magnetic field.

First valued as a tool to help organic chemists understand the structure of complex molecules, NMR spectroscopy has moved out of the chemistry laboratory in recent years and into a few major medical centers, as a still experimental method of diagnosing disease and imaging the interior of the human body.

EXERCISE VOLUNTEERS SOUGHT FOR HEART DISEASE STUDY

STANFORD—

A team of Stanford University investigators will attempt to learn whether a drug taken by millions of heart disease sufferers will interfere with their ability to get in shape via exercise.

Some preliminary experiments with rats have indicated that beta blockers, drugs given to lower blood pressure and oxygen use by the heart muscle, might impede the cardiovascular system's ability to become healthier through exercise, said Mike Savin, a research associate in the Division of Cardiology.

On the other hand, at least one study has indicated that the drugs might actually enhance their takers' ability to improve cardiovascular fitness, while still other work suggests that the drugs have no affect on fitness.

Beta blockers, sold under such names as atenolol and propranolol, are the most widely prescribed category of cardiovascular drugs, and account for about $370 million in sales annually in the United States, said Savin. They lower blood pressure and heart rate by attaching themselves to receptors at nerve endings in the body. The beta blockers serve as barriers to halt incoming chemical messengers which otherwise would tell the heart to speed up.

Elaine Gordon, a postdoctoral research fellow in cardiology, said it is possible that the interaction between the chemical messengers and the receptors—which does not occur while people take beta blockers—may be the stimulus causing improved fitness.

However, because of the inconclusive and sometimes contradictory data, Gordon said Stanford Heart Disease Prevention Program researchers are looking for 45 healthy but sedentary men between 20 and about 40 years old who will volunteer to take beta blockers while simultaneously starting an exercise program.

The volunteers will be divided into three groups. Fifteen volunteers will be given a beta blocker which works almost exclusively on the nerve endings in the heart (atenolol). A second group of 15 will receive beta blockers which are more general (propranolol) and will affect nerve endings in the heart as well as other parts of the body, Savin said. A third group will be given a placebo.

Potential volunteers must be in excellent health but should not have been involved in a physical fitness program for at least the past eight months, Savin said.

"We need to ensure that people are healthy enough to begin a vigorous exercise program, but we need people who are not in top shape so that they have margin to show measurable improvement."

-more-

All of the volunteers will be placed on a six-week personalized exercise program, consisting primarily of stationary bicycle riding. Progress will be carefully and continually monitored by researchers in a Stanford gym, the researchers said. Participants are expected to exercise for about 40 minutes, five or six times each week.

Neither the researchers nor the volunteers will know who is receiving drugs or the placebo, Gordon said. Volunteers will be given increasingly larger doses until their heart rate is lowered.

"At the end of the study, participants will receive extensive medical and fitness testing, and we will then compare if the placebo group showed more improvement than the volunteers taking beta blockers," Gordon added.

If the results show that healthy volunteers taking beta blockers fail to get in shape, "we will need to run further studies to learn if people who need beta blockers for therapeutic reasons are affected in the same way," Savin said.

The researcher said that the beta blockers pose no signficant risks to healthy volunteers, although participants may experience some minor discomfort. Among anticipated side effects, he said, is possible dizziness and lethargy, since their blood pressure could be lowered below normal levels. "These effects, if they occur, can be stopped immediately when the drug is discontinued," Savin said.

Gordon said persons who regularly operate machinery would be eliminated as volunteers, since they would be prone to some risk. Also to be eliminated are persons suffering from asthma or diabetes, since their ailment could be aggravated by the drug, she said.

Potential benefits to volunteers "include the very strong possibility that they will be able to get in good physical shape. We are offering an extensive, well organized exercise program."

"If we find that volunteers in the group receiving beta blockers have failed to make physical improvements, we will work with them after the study to begin a personalized program off the drugs," Savin said.

Subjects will be paid $200 for the duration of the study, including $25 after the initial physical screening and a pre-exercise physical fitness test. The remaining $175 is to be paid after the test is completed.

Potential applicants are invited to call Savin or Gordon at (415) 497-6461 for further information or to enquire about an orientation meeting to be scheduled before the end of August at Stanford Medical Center.

The experiment has been approved by Stanford's Medical Committee for the use of Human Subjects in Research.

Researchers, in addition to Savin and Gordon, include William Haskell, clinical associate professor of family, community and preventive medicine.

PROMINENT FRENCH PHYSICIAN TO SPEAK ON PREVENTION OF PRETERM BIRTH

EDITORS:

Dr. Emile Papiernik will speak to the medical community on "Prevention of Preterm Birth," at 8 a.m. Friday, Sept. 3 in Fairchild Auditorium at Stanford University Medical School. Members of the press are also invited to this early morning session.

Papiernik, an internationally renowned pioneer in his field, is a professor of gynecology and obstetrics at the Faculty of Medicine, University of Paris.

His work of the last 15 years, on the early detection and recognition of preterm birth, has greatly contributed to a reduction in perinatal morbidity, mortality and birth defects.

Emphasizing patient self-care, Papiernik has encouraged physicians to listen to what patients say about their bodies.

Towards the end of his medical residency in the early 1960s, he received a gold medal from the University Hospitals of Pairs.

The upcoming talk, a regional perinatal event, is presented by Stanford's Department of Gynecology and Obstetrics, and the Mid-Coastal California Perinatal Outreach Program. A reception will be held courtesy of Astra Pharmaceuticals.

Anyone interested in attending the lecture should call Ria Church at (415) 497-5763.

RESEARCH PHYSICIAN CRITICIZES WILSON STROKE THEORY

STANFORD—

A Stanford researcher has seriously questioned a theory that Woodrow Wilson suffered a series of debilitating strokes in his pre-presidential years.

Dr. Michael F. Marmor, associate professor of ophthalmology at Stanford Medical School, had been asked by two Stanford Wilson scholars for a "second opinion" on the medical evidence. He has concluded that writer's cramp, neuritis or stress were more likely causes than a brain-damaging stroke for a series of ailments Wilson himself reported in correspondence to friends, relatives and physicians.

Marmor, writing in the Aug. 26 issue of the **New England Journal of Medicine**, questioned the methods and conclusions of Edwin A. Weinstein, a psychiatrist and emeritus professor of neurology at Mt. Sinai Medical School in New York. In a 1970 article in the **Journal of American History** and in a 1981 biography, Weinstein contended Wilson suffered a long series of incapacitating strokes starting in 1896 when he was 40 years old. These episodes, Weinstein said, may have been responsible for Wilson's enigmatic behavior.

"I question his (Weinstein's) presentation of evidence and his interpretation of it, and conclude that strokes were very unlikely prior to Wilson's severe stroke in 1919" which left the 28th president permanently paralyzed and disabled, Marmor said in an interview.

"A major problem," he continued, "is that Weinstein has presented a hypothesis as if it were accepted fact—and this theory has found its way without qualification into important historical documents. Future scholars will be severely misled if the record is not corrected.

Marmor, an ophthamololgist specializing in retinal disease, focused most closely on a 1906 episode when Wilson had complained of visual loss in one eye. Weinstein asserted unequivocally that the incident was a major stroke, but Marmor said "historical evidence—which Weinstein failed to report—shows the condition was a retinal hemorrhage which essentially rules out the diagnosis of an acute carotid stroke."

However, Weinstein, contacted by phone in Bethesda, Md., agreed Wilson had suffered a retinal hemorrhage which he said "was a manisfestation of carotid artery disease . . . .(Marmor) doesn't understand carotid artery disease."

(Weinstein said Thursday, Aug. 26, that he was unaware of the journal article. He added he would draft a reply to the article after he had a chance to read it).

-more-

Complaints in 1896 by Wilson of arm and finger pain and numbness was more likely writer's cramp than the initial stroke postulated by Weinstein, Marmor wrote.

Weinstein said the diagnosis of "writer's cramp" was "very vague," and he reaffirmed that a stroke was the likely cause.

Marmor said both he and Weinstein had access to the same evidence, which consisted largely of letters to and from the Wilson family, as well as later reminiscences.

Marmor noted, "These data are inadequate for definitive diagnosis. There are various possibilities and none—including stroke—should be viewed as accepted fact.

Referring to the evidence, unreported by Weinstein, of Wilson's eye hemorrhage, Marmor said in the article that "an omission of this magnitude is indefensible on scholarly grounds, and is particularly dangerous since the average reader (who lacks access to the primary sources) will assume that the data has been fairly presented, and will not realize that alternate interpretations are possible."

He said that while early strokes were not impossible, they were less likely than other alternatives, and "in the absence of clear evidence to the contrary, the most reasonable diagnosis for a historical figure is the most prevalent and ordinary condition.

"There is no better application for the old medical school adage, 'When you hear hoofbeats, don't think of zebras,' " Marmor said.

Weinstein, on the other hand, said that "to the best of my knowledge, all of the evidence points to my published conclusions" of pre-presidential strokes.

Marmor undertook the project because he had been asked to review available evidence by Alexander and Juliette George, co-authors of a personality study of Wilson. Alexander George is a professor of political science at Stanford.

The Georges said they were anxious for a second medical opinion on Wilson because Weinstein's theory had been picked up as fact in notes accompanying Arthur S. Link's 40-volume compendium of Wilson's papers. The work of Link, a professor of American history at Princeton, is considered the definitive historical collection on Wilson.

Juliette George said it was important to offer criticism of Weinstein's work, since it was in danger of being perpetuated as fact in the historical record.

The stroke theory has been used as a core for offering possible motives for Wilson's behavior.

Weinstein theorized that neurological damage was responsible for Wilson's self-defeating stubbornness at critical times in his life.

The Georges contend that Wilson's sometime "very stubborn" behavior was an integral part of his personality.

STANFORD—

A method of peering beneath patients' bones to diagnose disease in soft underlying organs—those not easily seen in X-rays—will be the focus of a news briefing at Stanford University Medical Center today, September 3 at 10 a.m.

Advances in the diagnosis of degenerative nerve diseases such as multiple sclerosis, and clearer ways of distinguishing between cancerous and normal tissue deeply embedded in organs such as the brain, liver, and heart are just two of a rapidly growing number of clinical applications for studies of nuclear magnetic resonance (NMR) - the tendency for the core of atoms to vibrate when placed in a strong magnetic field.

"NMR imaging is an exciting tool with a lot of potential," said Joseph P. Kriss, professor of radiology and chief of the division of nuclear medicine at Stanford.

"It introduces many more possibilities beyond strict anatomical information. You begin to combine anatomical data with information about the movement and biochemistry of molecules (within the body)," he said.

Kriss will address physicians and interested community members on "NMR from a Clinician's Perspective," as part of an afternoon-long symposium on the medical uses of NMR , following this morning's news conference.

The symposium, which will cap the six-day "Tenth International Conference on Magnetic Resonance in Biological Systems," will be held in Fairchild Auditorium at the Medical School from 1 to 6 pm. Members of the press are welcome to attend the symposium, which will feature experts in NMR from the United States and England, discussing both the principles and medical applications of NMR.

Like computer tomographic or "CT" scans—pictures constructed by a computer that stacks a series of X-rays—an NMR image reveals a slice of the body along any axis by compiling multiple scans taken several times each second.

Unlike a CT scan, an NMR image can be made without potentially hazardous X-ray radiation. Bones, outlined in X-rays, disappear from an NMR scan, to reveal the inner workings of blood vessels, and internal organs. Lungs, which often obscure pictures made via ultrasound imaging, prove to be no barrier for NMR.

The intact spinal chord, encased in its bony vertabrae coat, can't be seen at all via conventional X-rays or ultrasound, but can be studied in vivid detail using NMR imaging.

-more-

NMR is a classic example of a basic research experiment that turned out to have broad practical and commercial value totally unknown to the experimenters.

The work stems from research into the magnetic properties of atomic nucleii.

The protons of atoms spin like tops, a spin that produces a magnetic field. If external magnets are placed at right angles to the proton's magnetic field, the proton will flip over toward the magnet, and then quickly right itself.

In 1945-46, two teams of experimenters, one led by Felix Bloch at Stanford, the other by Edward Purcell at Harvard, demonstrated ways of detecting "resonance." Since the protons absorb radio waves at a particular fequency, it was possible to measure the length of time it took the protons to resume their usual attitude. Bloch and Purcell shared the 1952 Nobel prize in physics for this work.

The practical uses of NMR were not immediately obvious. Nonetheless, in 1948 a group of physicists in the Stanford physics department, led by the Varian brothers, formed a company, Varian Associates, with essentially two assets: the Varian patent on the klystron, which generated microwaves, and a patent on Bloch's work with NMR.

A group headed by Martin Packard was producing NMR devices in the Stanford lab to detect the resonance. One day in 1951 they were preparing a hand-made instrument when an Indian post-doctoral candidate, S. Dharmati, asked what would happen if Packard put an organic liquid in the magnetic field. He worked up a concoction of ethyl alcohol.

Chemists believed that ethyl alcohol contained three clusters of hydrogen atoms in its molecule, but had never actually seen them.

When the experiment was run, the device clearly showed jumps in the graph for three clumps of hydrogen in exactly the proportion chemists envisioned.

Since each element apparently has its own resonance properties, it was apparent that this was a good way of making chemical analyses in laboratories.

In the ensuing years Varian produced a whole family of NMR devices, which became standard for scientific research. When the patent expired, other companies joined in the business.

Only in the last few years, with advances in technology, particularly computers, has NMR's other potential uses received considerable attention.

Rather than replace other imaging tools such as X-ray CT and ultrasound, NMR imaging is carving out its own niche in diagnostic medicine, permitting physicians to see living organs in ways never before possible, said Paul Lauterbur, professor of chemistry at the State University of New York and early pioneer in NMR imaging.

"It (acceptance of NMR) seems to have passed the threshold more or less within the past year or so," Lauterbur said, "from very much a 'wait and see' attitude to what seems to be a certainty on the part of a large segment of the radiological community. It's going to have a role that's at least comparable to X-ray CT.

-more-

"This is a very exciting era for medical diagnostic imaging," he added.

Just over a period of a couple of decades, physicians have gone from having only a very dim partial view of the anatomy of the body, to many ways of having a very detailed view of the inside of the body."

In addition to its role in diagnostic imaging, the NMR spectrometer is being used by physiologists and biochemists to study the energy use of cells, muscle tissue, and whole organisms.

While spectrometers used in imaging rely on the properties of water molecules in different tissues to create contrasts between dense tissues and tissues that are less dense, the instruments used in metabolism studies focus instead on compounds containing isotopes of phosphorous and hydrogen.

Critical to the ability of living organisms to convert nutrients into useable energy, the changing levels of phosphorous compounds in various tissues are good indicators of a healthy metabolism.

"Here the NMR method is essentially an assay method for determining concentrations of these compounds in the tissue," said Oleg Jaretzky, professor of pharmacology and director of Stanford's magnetic resonance laboratory. "It's main advantage is that it is completely noninvasive and nondestructive.

"The principle application, I would say, is going to be in looking at control mechanisms of metabolism in normal people, and also in those with disease," he said. "Where there is derangement of control, it is going to be very useful to monitor things without destroying the tissue, and without interfering with the process."

Current methods of studying metabolism are indirect, relying , for example, on measurements of enzyme levels in blood or tissue biopsies, he said.

"Those measurements tell you that something has gone wrong," Jardetzky said, "but they don't allow you—or at least not as easily— to follow all of the reactions that are relevant simultaneously or to watch the response to some modifying agent.

"When using current (indirect) methods, there is always a lag in time," Jardetzky said. "If you have to kill the tissue and grind it up to determine the compounds, you can never be sure that you have not really changed the relative concentrations, because these control mechanisms are relatively subtle

"NMR is extremely useful in discovering these subtle changes," he said, " to be able to watch things in vivo without disturbing the system at all."

SYMPOSIUM ALERT: CURRENT PRACTICES IN NUTRITION

STANFORD—

Dr. Allen Cooper, associate professor of medicine, and Jo Ann Hattner, perinatal nutritionist, will be among the speakers for "Recent Advances in Nutritional Care," a Department of Dietetics symposium to be held Oct. 5 in the auditorium of Children's Hospital at Stanford.

Also making presentations will be Dr. Michael Mequid from the City of Hope National Medical Center in Duarte, and Judith Ashley, nutrition consultant from Los Angeles.

The symposium of current practices, intended for dietitians, nurses, pharmacists, physicians, medical students, and allied health care professionals, will run from 8 a.m. till 1 p.m. It is open to the public.

Topics will include "Current Practices of Nutritional Support of the Cancer Patient," "Nutritional Support of the Pediatric Oncology Patient," "The Compromised Neonate: A Look at Prematurity and its Nutritional Challenge," and "Dietary Cholesterol Metabolism: The Molecular Basis for Practical Considerations."

Pre-registration deadline for the symposium is Sept. 24. For further information regarding fees, continuing education credit, and program objectives, call Jane Woeckener, R.D., at 497-6904.

TEENS TAUGHT TO LOSE WEIGHT SAFELY

STANFORD—

Stanford's behavioral medicine program is offering a weight-loss course for teenagers, ages 12-17, on the University campus during the fall quarter.

Encouraging students to take charge of their own weight management, the program will teach them to lose weight safely through eating and exercise patterns that promote permanent weight control.

The program, intended specifically for teenagers, will include group seminars in behavioral change techniques and nutrition education; aerobic activity; group meals on campus; and monthly seminars for parents.

(An important feature of the program is consistent weight-loss management achieved through personal habit change combined with parental support at home.)

Faculty will include staff from the behavioral medicine program of the School of Medicine.

The sessions will run from 3:30 till 5:30 p.m., Wednesdays, Sept. 22 through Dec. 7. A program fee will be charged.

Early enrollment is recommended, as space is limited. For further information call Dr. Mary Southam, at 497-5065.

FEDERAL MEDIATOR TO STEP IN AT STANFORD

STANFORD—

A commissioner from the Federal Mediation and Conciliation Service will meet Friday, Sept. 17, with representatives of United Stanford Workers and the University to "try to get movement toward a settlement" of the strike by technical, maintenance, and service workers at Stanford, now in its sixth day.

Commissioner Dorothy Christiansen confirmed Wednesday, that she would meet for voluntary mediation at 10 a.m. Friday, Sept. 17, at a location to be selected by Michael Baratz, executive secretary of Local 715. Baratz initiated the request for FMCS assistance.

Christiansen said University labor counsel Prisciila Wheeler agreed to the plan. Christiansen's role will be to "act as an interpreter and objective observer." She has no power to impose a settlement on the parties, she said. FMCS is an autonomous agency of the federal government.

Baratz said he requested the mediation because it was "clear in the University response to our request (to return to the table) that they weren't prepared to negotiate in good faith. We needed another mechanism. We want to try to settle," he added.

Meanwhile the number of workers staying off the job Wednesday remained stable at about 800 or approximately 73 percent of the bargaining unit.

USW leaders pulled pickets away from construction projects, redeploying them to high visibility locations on campus.

Baratz said USW wanted construction workers at the 800-unit student housing project to proceed with work on the complex. Work also continued at the Braun Music Center and Cardiovascular Research Building. Contractors reportedly were seeking an injunction against picketing.

USW pickets Wednesday shut down work on an addition to the test laboratory at SLAC for the first time. Approximately a dozen employees of the contractor refused to cross the picket line on the grounds that the Alpine Road entrance to SLAC did not qualify as a "reserve gate" because SLAC employees were using it.

According to Stanford Police Chief Marvin Herrington the campus was "relatively quiet" Wednesday.

Pickets stopping or delaying vehicles was the biggest problem, he said.

Two stink bombings were reported at about 2 p.m. at Bonair Siding. Police said a private vehicle and a University truck were somehow doused with a pungent substance, possibly butric acid, when their drivers crossed the picket line. Police have no suspects.

USW has scheduled a meeting/rally for members at noon Thursday, Sept. 16, at the Bonair Siding parking lot.

STANFORD—

A filmless x-ray system intended to make certain diagnostic procedures safer while simultaneously making patient care more efficient was installed this week at the Stanford University Medical Center.

The new system, called digital fluoroscopy, employs a television camera which projects the image of the particular body part or tissue under study on a video screen. The picture is created from digital, or computer data, which allows the patient's picture to be stored on video or magnetic tape to be called up later by the doctor who can view it on a video screen.

"Within the next ten years, we expect systems employing video to totally revolutionize X-ray as we know it now," said Dr. Dieter Enzmann, head of the digital fluoroscopy program at Stanford.

The current system, manufactured by the General Electric Co., is expected to be in use treating patients by the end of October, Enzmann explained.

It was on display for approximately 400 persons attending the Sept. 14-15 Conference on Digital Radiography sponsored by the International Society for Optical Engineering, Stanford's Department of Radiology and the federal Bureau of Radiological Health.

Specifically, the device will be used initially for patients suffering from various blood vessel ailments.

Digital fluoroscopy enables good pictures of arteries to be recorded without the risk of inserting catheters (tubes) near the heart or brain. Such intrusions deep into the blood vessels to inject a dye could result in heart attacks or strokes.

In digital fluoroscopy, the dye, which is used to highlight the arteries, is injected into the veins in the arm, which is much less dangerous, simpler, and thus may be performed as an outpatient procedure, said Enzmann.

The individual picture produced of a blood vessel or soft tissue is not as detailed as the view produced from traditional catheterization.

-more-

But, Enzmann pointed out, the diagnostic capability is approximately the same, since the video console permits an imaging technique called subtraction.

First a picture of the patient is taken without a dye.

Then the same view is taken with the dye. The two views are combined on the screen in such a way as to eliminate unwanted structures (body parts), allowing the physician to observe areas of interest.

Hospitals may add the video camera and display console to their existing X-ray suite for about $200,000. Thus, Enzmann said, it is economically feasible now for use in many hospitals.

In addition, it provides potential efficiency and cost saving advantages for the hospital, patient, and the nation.

One of the largest savings, Enzmann said, is that hospital beds will be freed, because patients need not be hospitalized overnight as is necessary with catheterization.

"Eventually expensive X-ray film will be eliminated, and patient X-rays will be stored in a variety of ways, including digital and video disc and magnetic tape. Ultimately this could save hospital storage space and would be cheaper than film, but technological developments still are necessary for this development to become feasible," he said.

Within the next decade, Enzmann predicted it will be practical to transport X-ray pictures via cable to various locations, allowing a consulting physician in a nearby hospital, for example, to quickly view a patient X-ray transmitted to his own video terminal.

Other pioneering techniques in X-ray will also become increasingly available in the coming years.

One such system is "dual energy imaging," which is being used experimentally at Stanford under the direction of Dr. William Brody. This technique involves two nearly simultaneous X-ray photos of the same area taken at differing energy levels. The computer then constructs a picture on the video screen of the artery or material of interest to the physician.

FOR IMMEDIATE RELEASE

KENNEDY CANCELS EMPLOYEES DAY

STANFORD—

President Donald Kennedy of Stanford Thursday, Sept. 16, cancelled a planned Employee Day program preceding Saturday's football game with San Jose State, citing the risk of "serious disruption" by striking United Stanford Workers.

Picketing in the seventh day of the walkout by 800 workers focused on television trucks preparing to broadcast the game from Stanford Stadium.

The regional CBS telecast, scheduled to start at 1 p.m. on KPIX (Channel 5) provides $600,000 in revenues, divided among the two universities, and their respective conferences. Stanford's direct share is $192,000, with another $108,000 shared by the PAC-10 conference and other member institutions. San Jose State and the Pacific Coast Athletic Association would share the remaining $300,000.

Supervisors and student athletes pitched in to help with pregame preparations. "It seems to be going OK," an Athletic Department spokesman said.

Federal mediator Dorothy Christiansen plans to meet off campus at 10 a.m. Friday, Sept. 17, with USW Executive Secretary Michael Baratz and University Labor Counsel Priscilla Wheeler for voluntary mediation, requested by Baratz.

Three pickets were injured by drivers Thursday, and two pickets were arrested for earlier strike-related incidents. None of those hit required hospitalization.

A SLAC technician was struck by a car which had stopped, then accelerated through the SLAC main gate. The driver, a job-shopper, was promptly dismissed by SLAC. The technician was taken to Kaiser in Redwood City, where x-rays showed no broken bones. He was sent home with a bruised leg.

Two pickets struck by a truck at the Medical Center were transported by wheelchair to the emergency room, where they were found to have knee abrasions. Two pickets were arrested on outstanding warrants, one for allegedly spitting on a student driver and the other for allegedly cracking an independent trucker's windshield.

In cancelling Employee Day, scheduled for 11 a.m. Saturday at Frost, Kennedy said USW had stated its intention to come to the party for the purpose of confrontation and had announced plans to invite people outside Stanford to help them.

"In any such confrontation, the possibility of more serious disruption is always present, especially since this strike continues to be marred by threats to nonstriking employees, by vandalism of personal and University property, and by a number of incidents of personal violence."

Baratz replied that "blaming us for his cancelling is irresponsible." He said the union membership had been clearly told not to provoke incidents and not to commit vandalism.

"If the mere act of people looking at him confronts him, then he has a very thin skin and no understanding of what's happening," Baratz added.

Union flyers suggest members planned to distribute leaflets and picket at Frost. "We will receive assistance from local union members throughout the Bay Area in the Saturday 'party,' " the flyers added. "Plan to be there—let the University administrators know how you feel."

Reporters estimated about 100 persons attended a union membership meeting called for noon Thursday at Bonair siding. Rain and threatening skies may have reduced attendance.

Construction on most major projects appeared to have returned close to normal. Some bus drivers refused to cross picket lines near the Medical Center.

HOSPITAL AGREES TO MALPRACTICE SUIT SETTLEMENT

STANFORD—

Stanford University Hospital (SUH) agreed Thursday (Sept. 16) to settlement of a lawsuit filed on behalf of an infant born in the facility's delivery room April 7, 1980.

The settlement calls for lifetime support for Anna Younger, a spastic quadriplegic who according to the plaintiffs "sustained severe and permanent brain damage" because she stopped breathing for some minutes in the first hour after birth.

Named as defendants are SUH, Dr. Joseph R. Hopkins and Mid-Peninsula Health Services, Inc., a member-owned health care organization where Hopkins practices family medicine and serves as medical director. The defendants have denied allegations of negligence. No personnel at SUH were identified by name in the suit.

The agreement, ratified by Santa Clara County Superior Court Judge Edward Panelli, calls for an annuity to be established for support of the child, who most recently lives in a Santa Clara County foster home under voluntary arrangements of her parents.

The suit was filed by Anna's mother, Jocelyn Cunningham, 34, an accountant. She and her husband, Charles Younger, 37, a computer programmer, were Los Altos residents at the time of their daughter's birth.

Support payments for the child are to start Oct. 1 at $81,960—and increase according to a predetermined formula annually. By the year 2002, the child will be receiving more than $275,000 per year, according to the complex formula.

SUH and its malpractice insurer are responsible for funding the annuity during the life of the child, estimated by medical testimony and actuarial data to be 76 more years.

Thaddeus John Whalen, professor of economics at the University of Santa Clara, stated in a declaration filed by the plaintiffs that the present cash value of the settlement—taking into account tax advantages and other economic parameters—was at least $8.1 million.

In addition to personal damages for the child, SUH was to split a $1.2 million payment with Hopkins and Mid-Peninsula. Of this figure, about $200,000 is to be used for the child's current medical expenses, $150,000 was earmarked as personal and economic damages for each of her parents, with the remainder of the money going for plaintiff attorneys fees, court costs and related contingencies.

A review of the delivery room records filed as an exhibit with the court by Dr. L.L. Trigiano stated that a pediatric resident had examined the child moments after birth and "concluding she (the infant) was normal, returned her to her mother's arms." Trigiano, a San Francisco physician, had been asked by the plaintiff's attorney to review medical records and examine the child.

"...At approximately one hour of age in response to a remark from the father of the child as to whether the child was living, the nurse in the delivery room called attention to Dr. Hopkins, the obstetrician (family medicine specialist), that the child was found to be flacid with no respirations and no detectable apical (heart) pulse.

"Cardiopulmonary respiration was begun immediately with an urgent call to the neonatal intensive care nursery for return of the staff with subsequent full resuscitative measures to the infant."

The baby was transferred to the intensive care nursery, Trigiano's review said, where a CAT scan indicated oxygen deficit and death of brain tissue. The child was discharged a week later but continued to receive frequent medical care at a variety of institutions.

Trigiano, who examined Anna on July 12, predicted she will require constant custodial care for the rest of her life.

STANFORD—

A new artificial pancreas is being used at Stanford University Hospital in efforts to help insulin resistant diabetics.

Dr. Michael Greenfield, an endocrinologist, said blood sugar level has been successfully controlled so far in six diabetics who volunteered to participate in a pilot study.

The experiment was started about six months ago under a grant by the National Institute of Health and the Nora Eccles Treadwell Foundation. Dr. Gerald M. Reaven, professor of medicine, is the principal investigator.

The artificial pancreas is a mechanical device which permits the patient's insulin needs to be monitored on a minute-to-minute basis. The machine calculates and then administers the precise insulin dose needed at various times of the day to maintain proper blood sugar level.

About 10 million Americans suffer from diabetes, a disorder in which the body is unable to properly oxidize carbohydrates—specifically blood sugar—because either the pancreas fails to produce sufficient insulin or the body is incapable of utilizing its existing insulin supply. The amount of insulin needed at any given time is highly variable, and depends on such factors as food intake (which supplies glucose or sugar) and amount of exercise.

In the Stanford program, patients are hospitalized for about two weeks. Volunteers are connected to the mechanical pancreas, where for 24 hours blood in minute quantities is drawn from one arm and analyzed by the machine. The device, which costs $50,000, vaguely resembles in size and appearance a battery charger used by service stations.

"The blood is analyzed for glucose level every 10 seconds and the appropriate insulin dosage is thus computed. Then the machine injects insulin into the other arm at the precisly computed dosage," explained Robert Solomon, a research fellow.

Greenfield said the technique "is particularly significant for the millions of non-insulin-dependent diabetics who previously have been treated unsuccessfully with other drugs.

"There are people whose bodies produce an average or only slightly below average amount of insulin. What happens, though, is that for some reason their system is unable to use their own insulin to control the amount of blood sugar.

-more-

2-2-2 "Physicians in the past sometimes gave them massive doses of insulin in order to try and control the diabetes. But that approach was not effective, because we didn't know how much the patient needed at a particular time of the day," Greenfield added.

During the past decade, these older diabetics have been treated with drugs intended to help their bodies utilize their own insulin. But Greenfield explained that these drugs, while often offering temporary relief, may not sometimes provide any longterm benefits.

(In contrast, diabetics whose bodies fail to produce sufficient insulin have been treated successfully for many years with insulin injections. Because their insulin needs are smaller and more predictable, doctors have found it easier to prescribe proper dosages for these patients, who usually are younger than the insulin-resistant diabetic.)

Solomon said that the amount of blood used during a two-week hospitalization would be about the same as a single blood bank donation.

About 21 artificial pancreas machines currently are being used nationally, but Greenfield said he believes Stanford is the only facility using the gear for treatment research into non-insulin dependent diabetes.

Greenfield and Solomon said the current volunteers all have shown significant improvement in their blood sugar as they are continued to be monitored by their private physicians and the Clinical Research Center at Stanford University Hospital.

Eventually, the researchers hope that a miniaturized version of the artificial pancreas might be developed, so that a patient's insulin dose might continue to be monitored and administered. But Greenfield said the predictions based on the two-week monitoring seem to work effectively for the group tested so far.

Solomon and Greenfield both said current research would have to be expanded if scientists are to learn why some people build up a resistance to insulin or if the resistance is the preexisting condition which hinders the body's ability to burn blood sugar or produce insulin efficiently.

Doctors, who hope to complete the study in about a year, are searching for additional volunteers.

Criteria include persons suffering from diabetes who are otherwise in reasonably good health. They should never have been treated with insulin before. The researchers would prefer persons who are not more than about 25 percent overweight.

The volunteers will be treated without charge, including free insulin supplies, Greenfield said.

Persons or referring physicians who wish to contact the program may call Greenfield or Solomon or Claude Lardinois at (415) 497-6973 or 497-6054.

HOSPITAL LAUNCHES NON-SMOKING CAMPAIGN

STANFORD—

This week marks the official "kick off" of the Hospital's new non-smoking policy, passed by both the Medical and Hospital Boards.

Activities throughout the week are designed to introduce patients, faculty, staff, students, and visitors to the present regulations, which clearly delineate smoking from non-smoking areas.

A poster campaign has begun, signs have been posted, and patient information is being distributed. A series of quit smoking classes for employees will begin this fall.

All Hospital employees are being provided with "non-smoking cards" to hand to persons smoking outside a designated area.

For a couple of days this week, a booth has been installed between the cafeteria and the patient admitting area to distribute informational materials, balloons, buttons, and other items. Those lunching in the cafeteria are treated to a clown performance in honor of the non-smoking campaign.

The general guidelines of the Hospital's new non-smoking policy follow:

- In public areas of the Hospital, including waiting rooms, cafeterias, public hallways and lobbies, smoking is not permitted except in specially designated smoking areas.
- Where smoking is not permitted, conspicuous signs stating this fact shall be posted in both English and Spanish or by a generally recognized no-smoking symbol.
- Smoking is not permitted in any Hospital elevator, escalator, or stairwell.
- Smoking is prohibited in any area of the Hospital where flammable liquid or gases or oxygen are in use or stored.
- Visitors are not permitted to smoke in patient rooms at any time. For patients, smoking is permitted only in specially designated areas. The exception to this rule is a patient in a private room unable to go to a designated smoking area. Such a patient may smoke in the private room only on the written order of a physician.
- If an unsafe situation exists (for example, a patient is affected by medication), smoking materials may be removed.
- Employees, physicians, and students are not permitted to smoke in patient rooms at any time. No smoking is recommended in meeting rooms and classrooms.

Dr. James Silverman, chief of staff, has stressed the importance of the physicians' role in implementing the new policy. "The concept of non-smoking needs repeatedly to be emphasized because of the disastrous health consequences which come with the habit," he said.

The non-smoking campaign grew out of concern expressed to the Department of Community Relations by patients and their families, according to director Jeanne Kennedy. At that point, an advisory committee for patient relations was established, reporting to Kennedy.

Evaluation of the non-smoking policy and its implementation is hoped to be completed by December.

For further information regarding this week's activities, or the non-smoking campaign in general, call Community Relations at 497-7167.

TWO STORIES: Lisa Ames (415) 497-6911

STANFORD—

Dr. Robert M. Zollinger, emeritus professor and chairman of surgery at the Ohio State University College of Medicine, will present the eleventh Louis and Dorothy Kovitz visiting professorship lecture at Stanford School of Medicine Friday, Sept. 24.

Zollinger will speak from 5:30 till 6:30 p.m. in Fairchild Auditorium. His topic will be "Islet Cell Tumors and GI Hormones." The lecture is open to the public.

Zollinger will also present the surgical grand rounds on Saturday, Sept. 25. He will discuss "Reflections on Gastric Surgery" at 8 a.m. in room M106. This talk will be geared towards medical and health professionals, and medical students.

Zollinger is former president of the American College of Surgeons and the American Surgical Association. He is one of the best known and widely respected surgeons of his generation.

Prior to joining Ohio State's department of surgery in 1946, he served on the faculties of Peter Bent Brigham Hospital and Harvard Medical School. He received his M.D. degree from Ohio State, and holds many national and international awards, honors, and honorary degrees.

The Kovitz lectureship was established in 1969 by Dr. and Mrs. Kovitz of Los Altos to bring outstanding lecturers in medical and surgical fields to the Medical Center. Dr. Kovitz died in 1979.

STANFORD—

Healthy volunteers are needed to serve in control groups for diabetes research being conducted by Dr. Gerald Reaven and associates at Stanford University's clinical research center.

To be eligible, volunteers must be between 30 and 70 years of age, male or female, and without diabetes.

Participants will be offered the following free of charge: an evaluation of blood sugar, insulin and cholesterol; routine health evaluation including liver and kidney function test, blood chemistry, cardiogram and physical exam; and meals during the entire study period.

Anyone wishing further information about the ongoing studies should call Clarie Hollenbeck, Ph.D., or George Liu, M.D., between 9 a.m. and 5 p.m., at 497-6973.

PROGRAM TO HELP CHILDREN AND PARENTS DEAL WITH PUBERTY

STANFORD—

Puberty can be a bewildering and traumatic time for children who don't understand what is happening to their bodies. To ease the transition into adulthood, Paula Maguire Duke, M.D., assistant professor of pediatrics at Stanford University School of Medicine, is offering two puberty education courses to boys and girls, ages 10-12, and their parents.

Often, puberty education isn't offered until children are already experiencing it, Duke said. "By that time, it's too late. Children need information about the changes that are going to happen before then happen. Unlike most other things, puberty is a very individual process. If children don't know what to expect, it can make them feel like an 'outsiders' compared with their peers."

"What we really need to stress is that there is a very wide range of normalcy," she said.

Educating children early, Duke said, may help to avoid negative body images that often accompany their developing sexuality.

For example, 1981 studies in a high socioeconomic area showed 65 percent of 12-year-old girls wanted to be thinner, and 73 percent of boys wanted to be more muscular. But, there are physiological reasons why pre-pubertal boys cannot develop large muscles, and why pubertal girls experience weight gain and increase in body tissue, Duke said.

The courses, which will not include any discussion of moral values, consist of two hour-long sessions at Children's Hospital at Stanford. The first is scheduled for October 27 and November 3. The second is scheduled for November 9 and November 16.

Parents are included, Duke said, because studies have indicated that up to 70 percent of children in that age group want to hear such information from their parents. Many parents forget what puberty was like, Duke said, and are uncomfortable or unsure of how to approach and discuss the topic.

The first session, for boys, girls, and parents, will include discussion of the physical changes and development of secondary sex characteristics. The second session will provide more detailed information, with separate groups for each.

Participants will be questioned about their knowledge, and their attitudes before and after the sessions.

The questionaires will indicate if children feel more at ease with puberty as a result of the early education.

"Our goal is to change the way children deal with puberty by intervening at an early age. If children, and parents, start talking about these issues early enough, by the time they need to discuss interactive sex they will feel more comfortable."

Duke has been researching puberty education for about five years. She was instrumental in incorporating sex education in Palo Alto Unified School District's seventh grade curriculum.

For more information, or course registration, call 415-327-4800, ext. 538.

Science writers and city desks: The press is invited to attend the scientific sessions.

STANFORD—

A day-long scientific symposium on advances in organ transplantation will be held Friday (Sept. 24) in the Fairchild Auditorium of the Stanford University School of Medicine.

The meeting, sponsored by the National Kidney Foundation and Stanford's Division of Nephrology, will present an update of present concepts of transplantation of kidney, heart, bone marrow and pancreas and of the underlying genetic and tissue typing principles.

Simultaneous sessions will be held for physicians and for nurses, technicicans, social workers and dieticians. The latter will be held in Room 101, Physics Hall.

The symposium, which will begin at 8:40 a.m., honors the memory of Dr. Samuel L. Kountz, a pioneer transplant surgeon who held faculty posts at Stanford, the University of California in San Francisco, and Downstate Medical Center, New York City, before his untimely death last December.

Among participants presenting reports are some of the leaders in the field of organ transplantation. Program details and topics follow asterisks.

* * * * *

9 a.m.	Hugh McDevitt, Stanford, "Advances in Genetic Organization of the HLA Transplantation System."
9:50	Carl Grumet, Stanford, "Advances in HLA Typing."

VOLUNTEERS SOUGHT FOR SLEEP STUDY

STANFORD—

The Sleep Disorders Research Center at Stanford University Medical Center is seeking about 25 volunteers suffering from insomnia or a related disorder to participate in a study.

Research assistant Sue Cohen said participants must be between 55 and 70 years old willing to take sleep medication. They must remain a total of nine nights and eight days in a Palo Alto lab, broken into two segments with an opportunity to go home between sessions. Volunteers are needed for two time period, Oct. 4-16 or Oct. 18-30.

Participants will be paid $300. In addition, they will be given free the results of two extensive physical exams conducted in conjunction with the research and will receive free all meals while at the lab.

The purpose of the experiment is to test the daytime alertness of persons taking Halcion and Restoril, two potentially widely applicable benzodiazapines. These medications, similar to Valium, are mild tranquilizers intended to relieve sleeplessness.

The volunteers will be electronically monitored at night to record their sleep habits. Cohen said various skill tests will be given during the day to test their alertness.

Volunteers will be divided into three groups, including those volunteers taking one of the two medications and a placebo group.

Insomnia sufferers are particularly being sought, Cohen said, while persons with narcolepsy, apnea or other longterm chronic disorders will not be accepted, Cohn said.

For further information, physicians or patients may call the sleep center at(415) 497-7134 or 325-4697.

FINANCIAL WORRIES CONCERN MEDICAL SCHOOL STUDENTS, ADMINISTRATORS

STANFORD—

Michael Laufer is worried. A third-year medical student at Stanford University School of Medicine, he had arranged to get a research grant for the summer. The grant would have given him remitted tuition benefits, enabling him to enroll for some classes without cost. But the funding fell through, and Laufer spent the summer working odd jobs, barely making enough money to scrape by. His savings, which he earned working as an engineer prior to entering medical school, are depleted.

Laufer receives the maximum amount of money from various grants to pay for his education. Yet he finds himself relying increasingly on loans to be able to meet his financial needs. Low-interest loans came through for him at the last moment this year. They had been delayed because of uncertainty of available federal funds. Next year, however, Laufer says he doesn't think those loans will be available.

Laufer could have planned to graduate in four years, but opted for five so he could work during school. By doing so, he hopes to keep the amount of his debts as low as possible. Not only will financial obstacles keep Laufer from graduating on time, but they may in fact influence his entire career, forcing him to choose a specialty that pays more or requires less training so he can pay back his loans.

"It's pretty depressing," Laufer admitted. "I deal with money problems on a crisis basis—facing them only when I'm forced to."

Laufer is not the only one worried. More than 80 percent of Stanford's medical students receive at least some financial assistance. Proposed federal legislation may result in a 50 percent decrease in available low-interest funding for student loans, according to the School's financial aid administrators' predictions.

In order to pay for spiraling living and educational expenses, budgeted at $20,000 this year, students are finding it necessary to consider alternative financing methods. Their parents' contributions account for an increasingly large share of the total budget.

Students and administrators alike fear that the number of applicants to medical school—at Stanford and elsewhere—will decrease. Those who do apply will most likely be from a more homogeneous segment of society.

"The impact of the cutbacks may decrease the diversity of our classes," predicted Dr. John Steward, associate dean of student affairs. "We worry that medicine may revert to being a profession that is the privilege of the well-to-do."

There is some evidence this may already be happening, said Katherine Kraus, financial aid administrator. She estimates the current first-year class parents are being expected to contribute 60 percent more than did last year's first-year class parents.

Because students who are not U.S. citizens or permanent residents are inelgible for federal loan funds, new admission policies require foreign students to deposit in a local bank enough money to cover four years' worth of expenses. At current rates, this amounts to about $80,000.

And Dr. Roy Maffly, director of admissions, estimates that three-quarters of those applicants who were accepted for the 1982-83 school year, and decided not to come to Stanford, based their decisions on financial reasons.

-more-

This particularly concerns Stanford, Steward said, which consistently has one of the highest percentages of students from minority and disadvantaged backgrounds. "This puts an extra heavy burden on our financial aid programs," he noted. "And with the School's goal of producing academicians and researchers, who are among the lowest paid in the field, we must provide enough aid to allow students to pursue these areas."

"This school is strongly dedicated to keeping its diversity," he stressed. "We'll do everything within our capabilities to include students from all backgrounds, and to encourage them to pursue careers in academia and research."

With this objective, the School takes as big an interest in students' financial situations as in their educations. Upon a student's acceptance, Kraus and her colleague, Stuart Rosse, use a standard needs analysis system to calculate how much parents are able to contribute, whether or not the student is independent.

First-year students are expected to contribute at least $700 from summer jobs, savings or other sources. Kraus and Rosse subtract these contributions from the individual budget to determine the students' needs.

Students are expected to borrow at least $3,000 per quarter, for a minimum of $12,000 per year.

As of now, the main loan sources include National Direct Student Loan (NDSL), at five percent interest; Guaranteed Student Loan (GSL) and Health Professions Student Loan (HPSL), at nine percent; and Auxililary Loan to Assist Students (ALAS), at 12 percent interest. Stanford also issues loans at up to ten percent interest.

Unfortunately, except for Stanford's loans, these sources are under the federal axe. New HPSL and NDSL allocations are unlikely for the future, Kraus said. And GSL, which provided about $1.5 of $2 million borrowed last year, is a "yearly fight to keep."

Formerly available to anyone, GSL eligibility has been made much more difficult since the government instituted a needs analysis system in 1981. Other loans, such as Health Education Assistance Loan (HEAL), are more readily available. But with interest rates at three-and-one-half points above treasury bill rates, students understandably try to avoid them.

Once students take out the required amount of loans, additional money—up to $2,000 per quarter—is available in cases of legitimate need from Medical School grants. Financial gifts are solicited primarily by the Office of Medical Development.

Of nearly $23 million received by the School in 1980-81, for example—of which medical alumni and associates gave about $254,000—about $1.5 million was earmarked for student aid, according to Sally Agle, deputy director of the Office.

Unrestricted gifts ordinarily are not used for financial support. However, a report prepared by the Office of Student Affairs warns that this year the reserve of financial aid funds will begin to be depleted. It also states that by the 1984-85 school year, in order to maintain the current level of assistance, money allocated to general operating budgets will most likely need to be used for financial aid. Stanford is the only one of its 13-medical school consortium that has yet to take this step.

"We've saved the reserves for a 'rainy day,' and this is it," Steward said. "Our financial aid programs are okay for a while, but truthfully, we aren't sure what will happen after the next couple of years."

"Luckily, we've had the foresight to plan ahead," Agle added. "In recent years the emphasis for gifts has been increasingly for students' financial aid. Private support is the main source of financial aid obtained through the Development Office. Until other sources can be identified, it is essential that individuals, such as alumni, realize the importance and necessity of their contributions."

-more-

"The problem," explained Laufer, who represents Stanford's medical students in the American Medical Association and the American Association of Medical Colleges, "is that the federal government perceives medical students as having a big earning potential, and not in need of as much aid as other students. What they don't realize is that during school we have almost no earning power. And during internships and residencies, medical students are working 60-100 hours a week for relatively low wages."

Most students graduating now have about $20,000 to $30,000 worth of debts, surveys show. Even with low-interest loans, payback estimates are about $500 per month. The average housestaff salaries this year, for example, are under $25,000 for the first four years following graduation.

"With living espenses, and possible loans from undergraduate schools to pay back, there is simply no way a medical student can afford to pay back large amounts of high-interest loans," Kraus said.

The Medical School does have other ways for students to finance their education, however. The Alumni Association's Medical Scholars Program and the Medical Science Training Program, for example, provide support for qualified students to do research.

The academic program gives students the flexibility—and many choose this route—to stay in school an extra year. Those working towards the M.D. degree are required to pay full tuition, currently $3,197 per quarter, for 13 quarters. After that, they are currently charged only $270 per quarter.

Stanford is also unique in that it encourages students to work while taking pre-clinical courses, especially in positions related to their interests in science or medicine. As a research or teaching assistant, a student not only earns a stipend, but has remitted tuition benefits as well. About 150 medical students took advantage of this opportunity during the 1981-82 school year, in addition to a variety of other jobs.

But even with these possibilities, some students feel there is a price to pay. "If you take extra time for school," Laufer explained, "it cuts down your earning potential and ability to pay back your loans."

And not all students think the opportunity to work is such a great idea. "Stanford is one of the few schools that encourage students to work while in school," said Cliff Greyson, a third-year student.

"It's fine if you're lucky enough to find a position in which you're interested. But the necessity to work, even if you don't like what you're doing, creates neurotic, unhappy people—especially when you're supposed to 'sleep, eat, and breathe medicine,' " he added, quoting a professor's welcoming remarks.

Gary Schwartz worked for a few years to earn some money before starting medical school. Now in his second year, he works as a research assistant in the Department of Medicine. He plans to spread out his pre-clinical course work for three years, so he can get tuition benefits through his work.

He'll have to quit his assistantship when he begins his clinical work, but at that point he'll only have one more quarter for which he'll have to pay full tuition. Schwartz has another problem, however. The financial aid administrators determined his mother should contribute $1,600 per year for his education.

"My mother is widowed and makes only $16,000 a year," he said. "I don't think it's fair to expect her to contribute at all."

So, Schwartz has been contributing her portion from his savings, in addition to his own contribution. "My savings are quickly being depleted, so I've resigned myself to having to take out loans."

Even so, Schwartz said, he'll be in his thirties by the time he finishes his training. "It's hard to live like a student and restrict your lifestyle until you're 35 or so. But," he added, "Stanford is doing a good job in giving me what they think I'm entitled to."

Not everyone is as appeased as Schwartz, however. Greyson has GLS, ALAS, and Stanford loans. He's worked as research and teaching assistants, and has always held summer jobs. His parents' contribution was set at $10,000 per year, but not wanting to take their money, he's provided their contribution as well as his own.

-more-

Recently however, his parents' financial status took a "nosedive," and Greyson suddenly finds himself available for much more assistance.

"It's ironic that even though *my* financial situation hasn't changed one bit, suddenly I'm elgible for so much more aid," he said.

Greyson said he doesn't need as much money as he's allocated on which to live. Others, such as those living in married student housing, are being subsidized on both ends. Meanwhile, those who need more money may have to resort to high-interest loan sources, he explained.

"Stanford has a limited amount of money to give," he charged. "It should be allocated through assistance programs tailored to individual needs."

In response to Greyson's criticism, Kraus said the School is bound by certain regulations in determining financial aid, but tries to tailor it as much as possible. "We are responsive to students' changing needs," she said. "We encourage students to live on less than the budget, hoping that perhaps they won't have to take out a high-interest loan. But most feel the budget is pretty frugal."

Greyson shares the feeling that future classes will be more homogeneous. "Those from low-income families can't afford to come to medical school," he said.

Laufer agrees. "Why should they bother? They struggle to get to medical school, struggle while they are in medical school, and struggle once they get out. It's just not worth it. They can make more money more easily in another profession."

The challange for the Medical School, then, is keeping the best students from opting for other professions. Students like Laufer are becoming politically involved to enlighten the federal government to medical students' plight. Administrators are continually seeking out new sources of financial support.

Meanwhile, they are trying to educate students in debt management, hoping to make them a little more at ease with the prospects. But for many, the bottom line is just how much an individual wants to be a physician.

"Students will have to make sacrifices, just as I and my classmates are," Laufer said. "But the end justifies the means. And with help from the federal government, we'll make it to the end."

STANFORD— **FETAL INFECTION MAY CAUSE DEFECTS YEARS LATER**

An infection acquired during pregnancy that is responsible for more birth defects than herpes, rubella and syphilis combined may be even more common and insidious than researchers first thought, according to studies by scientists at the Palo Alto Medical Research Foundation and Stanford Medical School.

Toxoplasmosis, a disease triggered by a parasite that passes across the placenta to cause blindness, deafness or mental retardation in more than 3500 developing fetuses in the United States each year, may lie dormant in some children, according to Jack S. Remington. These children appear normal at birth but as many as 90 percent will develop symptoms of the disease in their first decade of life, he said. Yet the disease, he emphasized, is preventable.

Remington, chairman of the department of Immunology and Infectious Diseases at the Foundation and professor of medicine at Stanford University, will present his findings at a world conference on the "Prevention of physical and mental congenital defects" October 10-16 in Strasbourg, France.

"Most people thought that these apparently normal babies (whose mothers contracted the infection late in pregnancy) were normal the rest of their life," Remington said. "Now we know that there may be a long latent period before the disease becomes apparent. Thus, there is a tremendous iceberg beneath the surface. If we could detect these babies early enough, there is some evidence to suggest that treatment early in life could prevent the damage that otherwise follows."

Nearly 50 percent of U.S. residents are chronically infected with the parasite *Toxoplasma gondii*, Remington said, though only a fraction of those suffer serious symptoms from their infection. Women who harbor the organism before they become pregnant (approximately one fourth of all women of child-bearing age) pose no danger to their unborn child.

But when a woman contracts the disease during her pregnancy, her child stands a 45 percent chance of acquiring an infection that can cause significant damage to vital organ systems, Remington said.

-more-

Currently no vaccine exists to inoculate women against the disease, though a simple blood test can detect the infection. While some countries require that blood tests for the infection be performed at least once during each trimester of pregnancy, most American women—and many of their physicians—don't even know the disease exists, Remington said.

"The message is that this is a major, preventable disease that is not appropriately appreciated by the public at large," Remington said. "You can't find a woman in Paris who doesn't know what toxoplasmosis is, but physicians in this country are not informing their patients. Women here don't even know about it so they can't prevent it."

Undercooked meat, unwashed vegetables, and cat feces are common transmitters of the parasite. If women take a few simple precautions while they are pregnant, they can greatly reduce their chances of acquiring the infection, Remington said.

Such precautions include avoiding raw and rare meat by smoke-curing or cooking above 151 degrees Fahrenheit, washing hands after handling raw meat or unwashed vegetables, avoiding contact with stray cats, letting someone else change the cat litter, and wearing gloves while gardening or working in the soil.

If a pregnant woman contracts the infection, she has several options which she should discuss with her doctor, Remington said, depending upon the seriousness of her infection. The choices include antibiotic therapy, therapeutic abortion, or risking infection of the fetus.

Results are still not in from all the international studies following children whose mothers were exposed to the parasite late in pregnancy, Remington said, but preliminary data indicate that such children who are identified and treated with antibiotics in the months after birth fare better than untreated children.

"We know that in animal models (the drugs given after birth) will eradicate the destructive form of the organism and cure the disease," said Remington.

"The important point that I wish to emphasize is that this is a preventable infection and a treatable infection," he said, suggesting that pregnant women insist upon the blood test and get additional information about the disease from their doctors.

POWER OF SUGGESTION HELPS HYPERTENSIVES RELAX

STANFORD—

Studies over the past few years have shown that muscle relaxation training can, at least for a period of time, successfully supplement medical treatment of high blood pressure.

A new set of findings at Stanford has led researchers to believe that patients' *expectations* influence the outcome of this therapy.

Hypertensive patients randomly assigned to two groups received three relaxation training sessions. Half were told to expect blood pressure lowering immediately; the other half were told that benefits would come gradually, after the first three sessions.

Dr. W. Stewart Agras, professor of psychiatry, reported in the Sept. 27 issue of *Psychosomatic Medicine:* "Participants given the expectation that the blood pressure lowering effects of relaxation would be delayed showed significantly less (initial) reduction in. . .blood pressure than those who were told that relaxation would produce an immediate effect."

Moreover, Agras concluded that cognitive processes have an "obscure" power to promote, or interfere with, relaxation techniques for hypertensives.

These techniques are taught to about ten patients sitting quietly in a group. They breathe deeply and slowly, sequentially tensing and relaxing all the major muscle groups of the body, while imagining pleasant scenes.

"It's amazing to me," said Agras, "how many people say they've never felt like that before!"

The major predisposing factors for high blood pressure, he explained, are heredity and overweight. "But now, chronic stress is also widely suspected as a contributing factor."

Agras said that the main dangers associated with high blood pressure are increased risks of stroke, heart attacks, and heart failure.

He recommends the relaxation procedure as an adjunctive method of treatment for hypertensives who respond poorly to pharmacological treatment. "But relaxation is not a replacement treatment," he emphasized. "Medication is still a must for most hypertensive patients."

Training in muscular relaxation, Agras said, usually takes about eight separate hour-long group sessions. Patients also practice at home for about 15 minutes a day, five days a week, with therapist-prepared audiotapes.

Participants, he added, are taught to detect their tension levels during the work day, and eventually can relax instantaneously.

-more-

The effects of relaxation training on hypertensives were first observed by researchers as far back as 50 years ago, Agras explained.

"Perhaps due to the discovery of effective pharmacological measures to reduce blood pressure, this method was largely ignored until the mid-60s when reports of the effects of meditation and biofeedback rekindled interest in the psychological treatment of hypertension."

In studies since then, relaxation training has been proven superior to placebo procedures in working with medication to help reduce high blood pressure. (Relaxation effects have not yet been directly compared to those of salt restriction, weight loss or exercise.)

"At Stanford we've been researching relaxation's effects on blood pressure since about 1975," Agras said. Once convinced of the training's immediate benefits, Agras and his team went on to demonstrate that they last around the clock, even under stressful work environments.

In Stanford's longest published follow-up study so far, Agras and his associates found that the blood pressure lowering effects of relaxation therapy on hypertensives persist for at least six months after the initial training series.

"These were people who continued practicing three to five times a week with audiotapes, and whom we met with monthly to retrain," he said.

Beyond that period, however, the effects remain to be seen. "Whether relaxation therapy affords long-term benefits is now the big question," Agras added.

Researchers also want to determine who benefits the most from the treatment. Agras suspects that those with hypertension most out of control or who've had the condition a long time will reap the most, with borderline patients benefiting little.

Besides helping to lower blood pressure, relaxation training has been found to effect dramatic drops in anxiety, depression, and "high-strung" behavior. Other investigators, Agras said, have discovered that relaxation therapy reduces insomnia and the pain of tension headaches. "So we're seeing the beginnings of a general stress reduction approach," he said.

"Although relaxation training is not yet an established form of treatment, it's to the point where there's enough evidence—at least of its adjunctive merit—that we're beginning to see its applications," he added.

Agras' study on expectation and the blood pressure lowering effects of relaxation was supported in part by a grant from the National Institutes of Health.

UNIT CLOSED IN RESPONSE TO HOSPITAL'S LOW OCCUPANCY

STANFORD—

A lower patient census than expected has forced Stanford University Hospital officials to close a nursing unit in the Hoover Pavilion last week.

The drop in patient census at the 663-bed hospital began in June. Normally during the summer months Hospital occupancy remains at about 75 percent or more. This year it dropped to about 66 percent in July and 69 percent in August.

"We are not the only hospital facing a low census, probably due in part to the overall economic recession," said Duane Walker, R.N., M.S., director of Nursing Services. "This is happening throughout California, the western states, and most of the country."

Sheldon King, executive director of SUH, said that the situation is parallel in many private doctors' offices. "With high unemployment nationwide, I would guess that many people have used up their medical insurance and are simply not seeking medical care unless absolutely necessary."

Another cause of the unusually low census, King said, is the Department of Health and Human Services' guidelines which approve the admission of Medi-Cal patients only in cases of emergency or function-threatening conditions.

Nursing Administration, Walker said, is working closely with the union, CRONA, to keep all of Stanford's permanent nursing staff employed. The clinical nursing coordinator and staff of the closed unit (N2A) have moved to other nursing units at Hoover and the main center. Surgical patients usually admitted to N2A will be accommodated elsewhere.

In closing N2A, a surgical unit specializing in sports medicine, Hospital administrators hope to allow other nursing units to provide cost efficient patient care by maintaining a fuller census.

King said that Hospital and Nursing Administration would examine whether another nursing unit should be closed in the near future. "Our reaction to the low census," he said, "must be to reduce resources to match patient needs." He explained that the first step taken on N2A was to reduce its operations to a five-day week.

Walker said that most of the nurses have responded well to the uncertainty that's prevailed throughout the underpopulated units. "One unfortunate aspect is that we're simply unable now to use most of our relief nurses, who have in the past provided a pool of people available to fill in and work certain hours as needed. Until recently we've always been able to utilize them."

Both King and Walker declined to predict when the situation might reverse itself, returning the patient census to expected levels. They think improvement in the economy, when that happens, will probably be the best indicator. Said King, "The number of Hospital reservations has increased again slightly, but not to any significant degree."

INVITATION TO SECOND ANNUAL SAFETY FAIRE

STANFORD—

Ever wish you knew more about preventing crime in your home, or that you were better prepared for accidents and earthquakes?

The Hospital's second annual safety faire, to be held the week of Oct. 18-22, should help answer these questions and more. All members of the community are invited to attend.

A different presentation will take place each day of the week, in the corridor outside the main center cafeteria:

- Monday is "Health Awareness Day," 10 a.m. till 4 p.m., with exhibits by the Pharmacy and Dietetics Department. The American Red Cross and Stanford Heart Disease Prevention Program will present exhibits as well.
- Tuesday is "Attack on the Back Day: The Stanford Back Trak," 7 a.m. till 5 p.m., to consist of a self-guided exhibit made up of several informational stations.
- Wednesday will feature "Patient, Employee, Chemical, Radiation Safety," from 10 a.m. till 4 p.m. Presentations will be made on radiation and chemical safety, hazardous wastes, and safety with sharp objects.
- Thursday is "Disaster Preparedness Day," from 10 a.m. till 4 p.m., with exhibits covering the 1906 earthquake, HAM radio operations, laboratory disasters, earthquake preparedness, plus a presentation by a renowned luncheon speaker.
- Friday will feature "Fire/Electrical/Rape Awareness/Protection in the Home," from 10 a.m. till 4 p.m. Displays by the Palo Alto Fire Department will include use of fire extinguishers, smoke detectors, and fire hazards at home. Fire extinguishers will be available for purchase. The Security and Clinical Engineering Departments will have displays on their services. "Blow the Whistle on Crime" is the theme for the day.

Film presentations during the week will include "Hospitals Don't Burn," "Rape: Preventive Inquiry," "Look Before You Eat," "Heimlich Maneuver," "Code 101," "CPR," "Code 10—Bomb Threat," and "General First Aid."

Showings will be continuous from noon till 8 p.m. on Wednesday, Oct. 20, in the Hoover Pavilion, room NC09; and from 10 a.m. till 8 p.m. Friday, Oct. 22, in the main center, room W003.

The faire is presented by the Hospital's Environmental Health/Safety Committee. Training sessions meet the in-service requirements of the Joint Commission for the Accreditation of Hospitals.

NCCP SYMPOSIUM ALERT

STANFORD—

A symposium on the mechanisms of resistance to anticancer drugs will be held from 9 a.m. till 3 p.m. Saturday, Oct. 23, in the Fairchild Auditorium at Stanford University Medical Center.

The second in a series of one-day symposia sponsored by the Northern California Cancer Program, the day's discussion will focus on alkaloids, antibiotics, and alkylating agents. Advance registration is encouraged.

Specific topics addressed will be "Overproduction of a plasma membrane glycoprotein in multi-drug resistance," "Multiple drug cross-resistance in mouse neuroblastoma cells," "Alkaloid resistance and cross-resistance in human leukemia cells," "Mechanisms of resistance to bleomycin," and "Mechanisms and modulation of resistance to alkylating agents."

Dr. Branimir Ivan Sikic, assistant professor of medicine (oncology and clinical pharmacology), will co-chair the event with Dr. George Stark, professor of biochemistry, and Dr. Victor Levin, associate director of the Brain Tumor Research Center at U.C.S.F.

Speakers will also include Drs. J.R. Riordan (visiting from University of Toronto, biochemistry), Fred Baskin (University of Texas), William Beck (St. Jude's Children's Research Hospital), and J. Martin Brown, associate professor of radiology at Stanford.

A box lunch, courtesy of NCCP, will be served. The symposium is supported in part by a grant from Adria Laboratories. For further information contact Martha Kaplan, at 497-7431.

MEDICINE AND COMPUTERS COMBINED IN DEGREE PROGRAM

STANFORD—

A graduate program integrating medicine and computer science has been established at Stanford University.

The melding of medicine and computer science has led to such recent innovations as helping doctors diagnose patient ills by using computers to analyze their symptoms and medical history.

The new Ph.D. and master's degree program in Medical Information Sciences (MIS) was approved Thursday (Oct. 14) by the Faculty Senate. University President Donald Kennedy praised Edward H. Shortliffe, assistant professor of medicine and computer science, for a "thoughtful, thorough, impressive" defense of the program before the senate.

Shortliffe is chairman of the interdisciplinary Committee on Medical Information Sciences which proposed the program.

Shortliffe said the normal pattern has been for M.D.s interested in MIS to get a Ph.D. in computer sciences after medical school. He told the senate that such an approach provided the physician with a "highly theoretical" computer orientation often failing to relate effectively to the clinical environment.

Although Stanford has been training a handful of students in the dual discipline of medicine and computer science for several years, Shortliffe explained "that one of the big problems was meeting the numerous requests from students who want to study medical information sciences at Stanford. While the expertise exists here, previously there was no formal program for them to apply to (although formal MIS programs exist at a few other schools around the nation.)

"Perhaps equally important, there was no structured curriculum to channel students' efforts once they arrived here with an interest in the field."

Shortliffe said about 45 potential students, mostly M.D.s, have inquired about the program since its development was made known several months ago.

-more-

The new program will be oriented toward persons interested in research and an academic environment, Shortliffe said. During the first year, he said, the program expects to attract two Ph.D. and two master's candidates.

Transfer students can start the program this year, with new admissions to begin in the fall of 1983.

Among potential students are physicians who wish to enhance their knowledge of computer science or of formal medical decision-making ability. Other students could be computer science majors with a background in biology or a related field who wish to make a commitment to medical information.

Ph.D. and two-year M.S. programs, according to the committee, are intended primarily for persons who are medical students or who already have an M.D., as well as other students seriously interested in MIS as a career.

A limited one year master's program is intended, Shortliffe said, as supplemental training for researchers who want a background in computer decision making to facilitate their work.

"We are hoping to develop a small cadre of students who will enter this program with a commitment to stay in the medical computer field.

"Without the specialized degree which this program offers, students who combined the two disciplines on an informal basis often were enticed into other areas of the rapidly expanding computer science field," Shortliffe said.

Members of the committee, in addition to chairman Shortliffe, include Bruce G. Buchanan, adjunct professor of computer science; Edward A Feigenbaum, professor of computer science; Michael L. Genesereth, assistant professor of computer science; Richard L. Popp, professor of medicine; Allen K. Ream, associate professor of anesthesia; Harold C. Sox, associate professor of medicine (clinical); Gio C.M. Wiederhold, assistant professor of computer science; and Leslie Zatz, professor of radiology.

A NEW ANSWER FOR MILD HEARING LOSS

STANFORD—

A new non-electronic hearing aid, which provides as much improvement as listening to speech or music with one's hand cupped behind the ear, was unveiled by Stanford University School of Medicine researchers Monday (Oct. 18).

"The device, called an Earesonator, can be an answer for mild hearing loss affecting more than a million Americans," said Dr. Richard L. Goode, professor of surgery.

Goode and his colleague, Richard O'Keefe, worked on the Earesonator for the past four years to perfect it.

"So far 30 patients with mild hearing loss have been fitted with the tiny plastic device," Goode reported. "The patients studied with pure tone audiometry have shown improvement of 10 to 20 decibels at key speech frequencies."

The new device, designed to be custom-fitted and worn within the ear, was introduced as part of a scientific exhibit at the annual meeting of the American Academy of Otolaryngology and Head and Neck Surgery in New Orleans, LA.

The average external ear only resonates at the high frequencies between 2800 to 4000 Hertz producing 10 to 15 decibels of sound amplification, Goode explained in an interview. A hertz, or Hz for short, is a unit of sound frequency measurement.

"Essentially, the external ear provides no amplification for the middle frequencies of 1000 to 2500 Hz, which comprise a very important speech range," he said.

"When the Earesonator is inserted into the ear, it changes the opening size and volume of the ear cavity, shifting the resonant frequency downward. This provides a sound boost of 10 to 15 decibels in the important 1000-2500 Hz speech frequency range."

By adjusting the size of the opening in the plastic device, the Earesonator can be fine-tuned to provide maximum amplification at the frequency the patient needs most.

"Potential users," Goode said, "can get some idea of the improvement that can be obtained by listening to speech or music with their hand cupped behind the ear—something many people do regularly."

-more-

Goode said anyone with mild unilateral or bilateral hearing loss should be helped by the device. Most people would require two, one for each ear.

For binaural fittings, each device is tuned to a slightly different resonance peak to expand the useful bandwidth of amplification.

Goode said the Earesonator cannot provide the same amount of amplification as an electronic hearing aid. But in cases of mild hearing loss only a small amount of amplification is needed.

"These people don't feel they need a conventional electronic hearing aid since they only have trouble hearing at certain times, such as when background noise is present or the speaker's voice is soft or high pitched," Goode said. "At other times they may get along quite well. They don't want to bother or spend as much as $300 for an electronic hearing aid. Now there's a choice."

Goode said the Earesonator, estimated to cost $50, is actually an extension of acoustical in-the-ear devices that have been around since the mid-1800s.

"But none of these earlier models provided adequate amplification for a variety of reasons," Goode said. In fact, he obtained some of the old devices from the hearing aids museum at Kent State University in Ohio and tested them.

"They made wonderful earplugs," Goode commented. "This is because the earlier inventors did not fully understand acoustical principles and did not have the sensitive sound measuring instruments now available."

This is how a patient is fitted with the Earesonator at the Stanford Ear, Nose and Throat Clinic:

First, a pure tone audiogram is made to determine the patient's thresholds in the mid-range sound frequencies. Next an impression is made of one ear or both, and impressions and audiogram are mailed to a laboratory.

In three weeks, the finished devices made of butyrate (clear) plastic and methyl methacrylate, a material used in dentures, are mailed back to be fitted and fine-tuned.

For the time being the Earesonator is available for research purposes at Stanford and the affiliated Palo Alto Veterans Administration Medical Center only. But Goode hopes they will be eventually mass produced if a manufacturer is interested.

STANFORD—

Dr. Loren R. "Yank" Chandler, noted surgeon and dean of Stanford University School of Medicine from 1933-53, died Saturday (Oct. 16) in Palo Alto following a brief illness. He was 88 years old.

"Defying the average term for deans of five years, Chandler remained dean for 20 years. He graduated 21 classes of physicians from the San Francisco campus, many of whom have since gained national prominence," said Dr. Lawrence G. Crowley, vice president for medical affairs at Stanford University Medical Center.

Chandler saw the Medical School through the Depression and WWII. He was a favorite of both faculty and students. He believed a good faculty was the key to a good medical school.

"You can have all the buildings you want, but you must also have the experts—the masters who can make a thing so simple that the student wonders why he didn't think of it himself. You need experts who can teach. And good teachers will produce others, who at the same professional age, will be better than they were."

" Chandler was just as likely to have been the attending faculty member on surgical wards of a hospital as one to whom students turned to when they needed a friend to provide warm encouragement and guidance about future careers," said Dr. Dominick P. Purpura, dean of the Medical School.

Wrote the *San Francisco Chronicle* when Chandler retired from the deanship in 1953, "Yank Chandler has been a notable dean and his administration has lent distinction to Stanford's place in medicine."

Considered a leader in the development of medical education, Chandler was president of the Association of American Medical Colleges from 1941-42, and president of the California Academy of Medicine in 1942.

-more-

His leadership exceeded the boundaries of medical education, however. He was on numerous federal commissions, and in national, state, and local organizations. He was president of the Pacific Coast Surgery Association in 1954-55; president of the San Francisco Surgical Society in 1948; and a fellow in the American College of Surgeons. He was also associated with the San Francisco Medical Society, the California Medical Association, the American Medical Association (AMA), and the American Surgical Association.

In 1950, Chandler was one of three men appointed to a commission of the AMA to study the effects of the British National Health Science Act. He concluded that it would be a "folly" to institute such a plan in the United States.

During a sabbatical in 1955, Chandler organized the staff and was chief surgeon at the Albert Schweitzer Hospital in Deschappelles, Haiti.

Chandler was an advocate of prepaid medical care, and was instrumental in developing the California Physicians Service and Blue Cross.

Born in Fresno, Calif. in 1895, Chandler received his A.B. degree from Stanford in 1920, and his M.D. degree in 1923. He was a surgery intern and resident at Lane Hospital from 1923-25, and then went into private practice. He maintained his association with the Medical School as clinical professor of surgery. He was appointed associate professor of surgery in 1933, and full professor of surgery in 1938.

From 1959 until his retirement, he served as chief of surgery at the Palo Alto Veterans Administration Hospital, of which he was a key planner.

In 1959 Chandler was made honorary fellow of Stanford University, the highest and seldom bestowed honor of the University.

Chandler is survived by his wife, Elvia Beal; son Craig; daughter Loran McIvor; and grandchildren.

At Chandler's request, there will be no memorial services. According to the family, memorial contributions can be made to the Loren R. "Yank" Chandler Memorial Fund, c/o Stanford University Medical School, or any preferred charity.

PUBLIC INVITED TO PSYCHIATRY LECTURE

STANFORD—

"Psychobiology: New Approaches to Mental Illness" is the topic of a public lecture to be held 8 p.m., Thursday, Oct. 28, in the Sherman Fairchild Auditorium at Stanford University Medical Center.

Speaker for the special program will be Dr. Jack Barchas, Nancy Friend Pritzker Professor of Psychiatry and Behavioral Sciences at Stanford and director of the Nancy Pritzker Laboratory of Behavioral Neurochemistry. Dr. Thomas Gonda, professor and chairman of the Department of Psychiatry and Behavioral Sciences, will serve as moderator.

Admission to the lecture is free, and there are no reserved seats. The program will be sponsored by the Friends of Psychiatry and Behavioral Sciences at Stanford. For further information and to help the organizers plan for adequate seating, please call 497-6376.

STANFORD—

An election has been scheduled Nov. 5-6 on the issue of whether about 1,200 service and maintenance workers at Stanford University Hospital wish union representation.

The election was ordered earlier this month by the National Labor Relations Board following a petition by Local 715 of the Service Employees International Union AFL-CIO.

Eligible to vote are a variety of job categories, including nursing assistants, unit service assistants, housekeeping and dietary workers, and maintenance employees.

No employees are now represented by Local 715 at the Hospital, a wholly-owned non-profit subsidiary corporation of Stanford University.

The only union bargaining unit now at the Hospital is the Committee for the Recognition of Nursing Achievement (CRONA), which represents about 1,250 registered nurses.

At the University, a Local 715 contract covers a bargaining unit covering 1,350 workers.

COMMUNITY AWARD GOES TO LOCAL MORTUARY OWNERS

Editors: Photo available upon request if not included.

STANFORD—

Stanford University Hospital's first community service award has been presented to Charles and Rose Jones of East Palo Alto for what was termed "a lesson in lived compassion."

Mr. and Mrs. Jones, owners of the Jones Mortuary in East Palo Alto, were commended for their distinguished service to the Hospital and community. They were presented with a plaque in grateful recognition of their unique contributions.

Over the past six years, the Jones Mortuary has provided burial services, free of charge, for more than 100 SUH babies and stillborns less than 30 days old—a service many insurance companies do not cover. Director Charles Jones has made special arrangements and allowed discounts on his services in many adult cases as well.

Dean Robert Hamerton-Kelly of the Stanford Chapel remarked at the ceremony, "When I hear about people like the Joneses, I have two responses: humility, and exhaltation at an instance of such humanity, which makes us all feel better about the human race."

He added that what the Joneses do "lies beyond our ability to honor," and thanked them for a "lesson in lived compassion."

Presenting the award, SUH director Sheldon King said, "The Jones' generosity respresents devotion to the community beyond that which most of us are capable."

Dr. Lawrence G. Crowley, vice president for medical affairs, said that the Jones' reception is expected to be the "first of many occasions like this, for presenting community service awards." He added, "Without the help of volunteers, our tasks would be impossible. This type of service improves the overall quality of the Hospital's mission."

Present at the event along with other special guests were Mayor Fred Eyerly of Palo Alto, and Mayor Barbara Mouton of East Palo Alto.

Director of Community Relations Jeanne Kennedy explained how her office, in conjunction with the Chaplains Office and Social Services, had worked to bring about the award. A brass plaque, said King, will hang prominently in the Hospital to honor the award and list present and future recipients.

The Jones Mortuary's generosity is largely due to Rose's childhood memory of a baby brother's death, when her family could not pay for the burial right away. She hoped never to see another family go through what hers had.

"It was important to me to provide this service free of charge, because people don't always have the money," she said.

Charles Jones dedicated half of the award to his mother, who died last month. "I would have wanted her to see this," he said.

Last January, the Jones Mortuary was a victim of criminal arson. The destruction caused by the fire resulted in an estimated $250,000 worth of property damage. The Joneses said they hope their building will be ready for use again by November.

'SUPER DONORS' CUSTOM-MATCH BLOOD TO MEET SPECIAL NEEDS

STANFORD—

Les Chibana arrived at work three and a half hours late one day last month so he could help keep a leukemia patient alive for a week or more.

Chibana's commute from San Mateo to Palo Alto included a stopover at the Stanford University Blood Bank where he became one of a small but special group of "super donors."

The life-supporting blood removed from his arm was less than the usual one-pint donation, but through a procedure called "platelet apheresis" he was able to give, with no danger to himself, between six and ten times the number of platelets usually found in a pint of whole blood.

"Knowing that there's a specific patient who needs my platelets makes a big difference to me," said Chibana, a graphic designer. Even before donation, Chibana's platelets were earmarked for a specific patient whose needs were made known to him by an urgent phone call.

Through apheresis, donors can be custom-matched to recipients, reducing the risk of rejection and decreasing the adverse reactions that can occur when patients receive blood from many unmatched sources.

In the same way that a cream separator skims rich froth and leaves milk, the apheresis machine pipes blood into a centrifuge from one arm of the donor, separates the blood components by weight, and returns the majority of the blood—"rehomogenized"—to the donor. Only the component needed most—usually platelets or white cells—is removed.

Less than a pint of the volunteer's blood is out of his body at any one time, enclosed within the sterile, disposable plastic tubing of the machine. The platelets taken—about eight tablespoons—will be replaced by fresh cells from his bone marrow within 24 hours.

Because a smaller quantity of blood is drawn, a super donor can give blood components more frequently than a whole blood donor, who is advised to allow eight-week intervals to pass between donations.

Leukemia patients use most of the platelets and white cells gathered through apheresis at Stanford's blood bank, said Pauline Burn, apheresis coordinator. Last year 64 patients received components garnered through 439 apheresis procedures, she said.

Most patients who need blood only require that it be matched to their ABO and Rh type. But for patients who receive multiple transfusions (such as leukemic patients who can require up to ten units of platelets daily during a crisis period), the two-way matching is not enough.

-more-

Each time a person receives blood from someone else, he risks developing antibodies that can attack foreign antigens (such as those from a blood donor) and destroy the transfused platelets. After multiple transfusions with blood from different donors, the patient can become completely unresponsive to the new platelets, destroying them almost as fast as they are introduced.

The troublemakers in these cases appear to be human leukocyte (called HLA) antigens—protein complexes that stud the membranes of platelets and other cells. Vital to the immune system in helping the body distinguish between itself and foreign matter, such antigens can cause problems for patients receiving needed transplanted tissue such as a heart, a kidney, or multiple transfusions of blood.

As specific to each individual as his fingerprint, the pattern of genes that code for antigens could never be matched exactly between any two individuals except identical twins. Fortunately, a mismatch of most antigens appears relatively harmless to patients. By carefully matching for the HLA antigens, which are known to cause trouble, physicians can avert the patient's "seek and destroy" response to the transfused cells.

Siblings often provide the best HLA match, but when a patient's need outstrips a family's ability to give, their only resort is to seek help from volunteer donors.

Stanford maintains a computerized list of 640 volunteers who have been HLA typed and have agreed to donate a component of their blood if and when it matches a patient's tissue type.

Burn encourages all those who donate whole blood to consider becoming apheresis super donors. Restrictions on who can donate are the same for both kinds of volunteers, except that super donors are requested to refrain from taking aspirin for three days prior to undergoing apheresis. (Aspirin interferes with the clotting action of the platelets.)

The number of times a volunteer will be requested to donate varies, but a typical super donor will be called to give once a week for two or three weeks in a year, Burn said. The larger the super donor pool, the greater the likelihood that several matches can be found, and the smaller the burden on any single donor.

Additional apheresis products are sometimes available through exchanges with other blood centers, Burn said, but because of the problems involved in shipping these fragile products, it is important to have as many local donors as possible.

"With a base of 2,000 super donors we could meet well over 90 percent of Stanford patients' needs," said Carl Grumet, associate professor of pathology and director of the Stanford Transfusion Service. "However, there's a complicating factor.

"In the Bay Area, we could have 2,000 Caucasian donors, but if a Chinese patient came in who had a type that was extremely rare or nonexistent among Caucasians, we'd have trouble finding a good match. We really need more non-Caucasian donors." (HLA types are not strictly tied to race, but a few types appear more commonly in some ethnic groups than in others.)

The need for apheresis blood products is growing all the time, Grumet said. An even more urgent need for both platelets and white cells will develop within a few years once Stanford's bone marrow transplant program is established.

-more-

Often apheresis matching takes on the character of an intensely personal drama.

In late September the Blood Bank began selectively harvesting young red cells for Brian Pavon, a Bay Area six-year-old who has beta-thalassemia major.

In this rare disease, the oxygen-carrying component of the red cell is defective, withering and misshaping the cell structure and speeding its destruction long before its normal 120-day lifespan.

Because his body can't adequately replace the cells he needs to meet his body's oxygen needs, Brian must rely on monthly transfusions of packed red blood cells.

But the gift of life carries a nasty chaser: frequent transfusions poison the body with more iron than it can handle. While the short-term effects are few, monthly transfusions year after year take their toll on a growing body, and thalassemic adolescents and young adults often die of congestive heart failure associated with the accumulated iron overload.

Because red cells normally live up to four months, by giving Brian only the youngest red cells (neocytes) via apheresis, his transfusion frequency may be reduced by as much as a third, thus cutting down his risk of iron overload. If the procedure is successful, it will used for other thalassemic patients, Burn said.

The future of apheresis may be bright in further honing medical treatment, but its success depends ultimately on volunteer blood donors, she added.

"The key thing is having a larger donor base," said Fran Bliven, an apheresis nurse at the Blood Bank. "We can have all the expertise and technical ability to get a good HLA match, to get each patient the blood product he needs. But all that expertise is wasted if we can't get enough donors."

One typical recipient, a man in his early 50's, was treated with chemotherapy for a month at Stanford for his acute myelocytic leukemia. He needed platelets four or five times each week for three weeks last spring. Keenly aware of his family's debt to several strangers, the patient's son wrote the following open letter to volunteers who were donating platelets:

TO A BEAUTIFUL PERSON:

I am the son of the man you are donating platelets for. I and my whole family think you are a wonderful, wonderful person and with your help and the Lord's we have come a long way with this disease.

You know our family is very close, and I can't imagine living a day without my father being there with us. With your help it looks like he is going ~~to be here~~ for a long, long time. The doctors have got this disease under complete remission. In about ten days from today he will be coming home.

Thanks again. We love you!

BATTLE FOR CONTROL OF HEALTH CARE SEEN BY ECONOMIST

STANFORD—

"Physicians face the likelihood of several unpleasant battles for control of health care," warns Victor Fuchs, a respected Stanford University health economist and a leading figure at the National Bureau of Economic Research.

Among the battles is one that reflects a larger set of issues. "This battle pits university physicians and hospitals against community physicians and hospitals," he said.

"Biomedical research funds are flat or falling," Fuchs said. "Medical education support is dwindling and, increasingly, the university medical centers are looking for patient care to shore up their revenues.

"At the same time, these centers dread the notion of having to compete for patients in a tight economic environment. In many cases their concern is well justified. When it comes to delivering bread-and-butter care, the chances are the community physicians and community hospitals can render this care less expensively.

"On the other hand, community physicians also feel threatened. They see these gleaming medical centers, big and powerful, and they see the famous specialists, and they wonder how the medical centers will use their power, and whether it will be at the expense of community physicians and hospitals."

Fuchs expressed his views in a recent article in *Health Affairs*, a professional journal.

The Stanford economist said the conflict among physicians is exacerbated by the proliferation of activities at the frontier of medicine that should be done primarily in medical centers, but which increasingly are being undertaken in community hospitals.

"This proliferation frequently is bad economics and bad medicine," Fuchs wrote. "Eventually, this conflict is going to produce a need for better understanding, a ned for compromise, a need to realize the legitimate concerns of each part of the health care enterprise."

Fuchs said he is particularly concerned about what will happen to medical research.

"Without research, without advancing the state of knowledge, medicine will begin to run up against blank walls," he said. "There is only a limited amount of improvement in health that can be purchased by increasing the number of physicians or by adding hospital beds.

"The great advances have always come from figuring out better and newer ways of preventing or treating disease. Somehow there have to be enough funds generated in medical centers to support research and to employ faculty who are actively engaged in research."

Fuchs feels society would benefit from the evolution of a medical care system where academic medical centers concentrated on research, teaching, and activities at the frontier of medicine, and did only as much primary and secondary care as necessary for them to carry out their principal missions.

"Complex, tertiary care," Fuchs wrote, "should be limited primarily to regional medical centers because they provide the specialized services more efficiently, offer higher quality of care, and carry out the research that should accompany all innovations in medicine."

-more-

Internal battles for control of health care also take place, said Fuchs, and are not limited to the academic medical centers. It is a general problem within the entire health sector in which practicing physicians and the managements of their hospitals are also fighting for control.

Curiously, government has not been one of the chief contestants. "This may come as a surprise," Fuchs said, "because the battle for control of health care is often depicted as one of medicine against government.

"Unfortunately, the medical profession is not using this breathing space as creatively and as constructively as it might. This is a shame because, while the regulatory threat went away for a time, medicine should not think that it has disappeared forever. It could come back quickly and heavily."

Fuchs urges physicians and other health care specialists to try to understand the reasons for conflict and to work for change.

"Let practicing physicians concentrate on treating patients and on less intensive forms of care," he advised. "Let academic physicians in medical centers concentrate on teaching, research, and tertiary care and only as much primary and secondary care as is necessary.

"Unless the necessary compromises are struck, American medicine will be consumed with conflict in the years to come, and patients and society will be the major sufferers."

CONSUMER ADVOCATE TO ADDRESS ALCOHOLISM

STANFORD—

"Alcohol Use and Abuse: The Health and Social Consequences" will be the topic of a public talk 7 p.m., Nov. 8 in the Fairchild Auditorium, by Dr. Michael Jacobson, nationally known consumer advocate.

He will discuss ways for health professionals, community groups and individuals to help combat alcoholism. "Alcohol abuse costs society over $100 billion per year and results in an estimated 200,000 deaths of Americans annually," noted Holly Nickels, R.D., of the Department of Dietetics.

Some of Jacobson's suggestions, she said, include educational efforts, an increase in alcohol taxes, and building of coalitions to put pressure on legislators and the alcohol industry. He is also involved in pressuring the broadcast industry to ban liquor advertising.

Jacobson is executive director of the Center for Science in the Public Interest, a nonprofit organization based in Washington, D.C., active in nutrition education and government policymaking in food and health issues.

Under his direction the Center, along with 16 other health and consumer groups, recently appealed to the liquor industry to print health and safety warnings and ingredients on all alcoholic beverage labels, to contribute funds for public service messages to discourage drinking, and to halt marketing and advertising aimed at children and teenagers.

Jacobson's talk is being sponsored by the SUH Department of Dietetics, San Jose Peninsula Dietetic Association, and the San Mateo County Nutrition Council. Attendance is free of charge.

For further information contact Nickels or Jane Woeckener, at 497-6904.

STANFORD—

Stanford University has responded to issues contained in an Aug. 2 "office action" by the U.S. Patent Office which had rejected a genetic engineering patent application.

The patent application covers the products of basic gene splicing and cloning methods invented by Stanley N. Cohen, professor of genetics at Stanford, and Herbert W. Boyer, professor of biochemistry at the University of California at San Francisco.

Niels Reimers, director of Stanford's office of technology licensing, said the response addresses all objections raised by the Patent Office "and we anticipate it will result in issuing of the patent in the near future."

Reimers said the Patent Office confirmed receipt of the document on Monday (Nov. 1). The university had three months from the Patent Office's August action to respond.

Reimers said he could not predict whe a response would be available from the Patent Office.

The university's response included a 22-page amendment and remarks to the original patent application, as well as declarations by several scientists, including Cohen, Boyer and Bernard Weisblum professor of pharmacology at the University of Wisconsin Medical School, who said information contained in the application was "enabling"—accurate and detailed enough to permit other researchers to use the genetic engineering techniques described.

The attorney noted that issue had been considered crucial, since the patent application includes an incorrect interpretation about how a particular plasmid (a circular form of DNA) was formed during Cohen's and Boyer's original experiments.

However, Weisblum and the university contend that sufficient information was provided in the application to enable scientists to perform the basic genetic engineering process.

"The numerous publications subsequent to the filing of the subject application support the fact that by following the teachings of the subject application one can prepare functional plasmids and and clone foreign DNA," stated Bertram I. Rowland, of Townsend and Townsend attorneys of San Francisco, which prepared the amendment.

In addition, Cohen and Boyer had made the plasmid in question available to researchers, enabling them to apply the technique without regard to the description of the plasmid.

In addition to Cohen, Boyer and Weisblum, other declarations were offered in the case about the enabling issue by Stanley Falkow, chairman of the Medical Microbiology Department at Stanford; David Hogness, professor of biochemistry at Stanford; and David Helinski, professor of biology at the University of California San Diego.

-more-

The amendment also addressed what Rowland called the "Darwininian" rejection. This was raised by the Patent office which noted that a DNA process analogous to the one described in the patent can occur in nature under special circumstances.

"Based on the frequency of mutation and selection of individual species, the evolutionary process is statistically unlikely to have occurred in the time span which was available." The amendment continued by noting that "an evolutionary time scale of hundreds of thousands of years and not the lifetime of a patent" is not relevant to consideration of the application.

"The next objection," read the attorney's remarks, "concerns the question of whether Professor Robert Helling of the University of Michigan is a coinventor. Helling has declined to sign a disclaimer of co-inventorship. He also has declined to respond to queries from Rowland about what role he played in the invention, the document said. Although Helling had co-authored a journal article with Boyer and Cohen, "the doctrine that co-authorship is **prima facie** evidence of coinventorship has always been considered by this attorney to be mischievous," Rowland wrote. He also noted a recent case which he said ssupported that premisef

The patent application follows another issued to Stanford in 1980 which covers the basic techniques of gene cloning. The current application was filed in 1974 and covers products resulting from the use of the technique. (These products, called transformants, are the result of intermediate steps between the genetic raw material and the desired commercial product).

Seventy-three licenses have been issued by Stanford and UC on a non-excluive basis for reasonable royalties based on the gene cloning techniques, Reimers said. Income to Stanford and UC so far has reached about $1.4 million.

Two products recently became commercially availiable, including insulin and a swine vaccine.

The techniques are powerful research tools for analyzing the working of genes. They also make possible the construction of "bacterial factories" that can safely produce large quantities of compounds important in medical treatment and other fields.

Because bacteria theoretically could be engineered to produce almost anything created naturally by plant and animal cells, the tenchiques developed by Cohen and Boyer may have significant applications in such diverse industries as energy, chemistry and agriculture.

A VISION OF THE PSYCHIATRY OF THE FUTURE

STANFORD—

Imagine a psychiatric clinic of the future.

A patient comes to the psychiatrist's office, obviously in a severely agitated or depressed state.

A blood sample, or perhaps a spinal fluid sample, will be drawn from the afflicted person. The analysis of the substance will be put into a mass-spectrometer, a $175,000 sophisticated machine now found in a small number of psychiatric research laboratories.

Simultaneously, the psychiatrist will draw from the patient a clinical history of his mental illness. Then, on the basis of the history and testing, the psychiatrist will be able to discuss with the patient the disorder and the subtype that the patient has. From the testing they will be able to identify immediately the optimal drug therapy.

That pharmacotherapy, combined with psychotherapy, will provide more specific, rapid, and effective treatment.

This vision of the psychiatry of the future was described recently by Dr. Jack Barchas before an overflow crowd in the Sherman Fairchild Auditorium of the Stanford University School of Medicine. His talk on "Psychobiology: New Approaches to Mental Illness" was sponsored by the Friends of Psychiatry and Behavioral Sciences at Stanford University Medical Center. The talk centered around new developments in the area of behavioral neurochemistry and the ways in which the new information might impact on diagnosis and treatment.

Barchas, a professor and director of the Nancy Pritzker Laboratory of Behavioral Neurochemistry at Stanford, is considered a rarity among the 30,000 psychiatrists in the United States. This is because perhaps only less than two dozen of them, like Barchas, are devoting their professional lives exclusively to researching the basic causes of mental illness at the biochemical level.

Schizophrenia no longer pertains to just that old bromide of split personality, according to the newest research findings. "It is most likely," said Barchas, "several different illnesses, say half a dozen, that we lump together because right now that's the state of knowledge. But information is developing very rapidly."

His laboratory, with private and government support, he said, is totally absorbed in a scientific search to discover what happens in the brain to cause severe mental disorders, such as schizophrenia that affects one percent of the nation's population, depression which affects five percent, and various addictive states.

A key aspect of the search at Stanford is the involvement of several faculty members who work together in a collaborative way.

-more-

Barchas emphasized those cross connections which include a close collaboration between the members of the Pritzker Laboratory and the Stanford Mental Health Clinical Research Center, directed by Dr. Philip A. Berger, associate professor of psychiatry.

At the Clinical Research Center, patients can be studied in careful detail with excellent monitoring of clinical status. Patients there may also be studied in a medication-free state. "We all owe a great deal to these volunteers who are willing to enable studies to take place in the hope of preventing others from having similar problems," said Barchas.

"Half the beds in hospitals in the United States," noted Barchas, "are devoted to patients in one or another form of psychiatric illness. Forgetting the pain of the families involved, these diseases probably cost the country over $51 billion a year in lost productivity and medical costs.

"The issue of research funding for mental illness is an overwhelming problem. Researchers in the field of psychiatry have fewer funds available in real money than in 1969."

Barchas noted that the annual spending for mental illness research is $6 per patient compared to approximately $100 and $200 spent respectively for heart disease and cancer research. The absolute amounts spent on research in mental illness are low compared to that for other serious disorders.

He said there has not been a strong tradition for government policy to support research into mental illness with the vigor that occurs for other serious illness. The private sector has also not been as active and there is not the type of private support which exists in other areas of health.

"Yet there's been an explosion of knowledge which needs to be explored," he said. "The basic sciences of neurochemistry and neuroscience have developed important information that is now incorporated into psychiatric research.

"We're learning all sorts of things, such as what neurotransmitters are present and how they work biochemically and physiologically. There was very little study of these problems until a few decades ago."

At that time, one of the shining lights of discovery that opened a new vista into the complex mechanisms of the human mind was turned on by a Swedish scientist, Arvid Carlsson. During chemical analysis of transmitters in the brain, he noticed a previously unrecognized spot on a sheet of chromatographic paper. It had never been identified before, explained Barchas, and he quickly related it to adrenaline in chemical structure. The compound that Carlsson discovered was dopamine.

"That discovery had implications for a number of different diseases," Barchas explained. "We now know that dopamine is important in Parkinson's disease, a movement disorder.

"It may also be important in some forms of depression. Knowledge about dopamine has led to a whole new way of thinking about schizophrenia, which suggests that a relative excess of dopamine may be involved in schizophrenia or in its treatment.

"That information ties in with other evidence about schizophrenia which suggests that the disorder may have biochemical and genetic aspects."

-more-

Barchas described some of the work of the Nancy Pritzker Laboratory in terms of dopamine and mental disorders. Members of the laboratory recently were the first to purify the critical enzyme from brain which controls the formation of dopamine and to determine some of its characteristics, including a marked activation during stress. They believe that increase in enzyme activity is a result of the addition of a phosphate group to the enzyme.

Barchas described two of his collaborations with other faculty. The first is with Dr. Roland Ciaranello, associate professor of psychiatry, with whom it was demonstrated that the amounts of the enzyme are controlled genetically. With Dr. Lawrence Kedes, associate professor of medicine, and postdoctoral fellows in his group, it has been possible to investigate the molecular genetics of the formation of dopamine.

Drs. Barchas, Ciaranello, and Kedes are now involved in a study of the processes regulating the formation of dopamine. The three of them, in association with Berger, expect to extend their studies on patients to determine whether individuals with schizophrenia, depression, autism, or borderline schizophrenia have changes in those genetic mechanisms.

The combination of basic science and an appropriate clinical environment is a critical factor in the effectiveness of the Stanford program, Barchas said.

New medications, Barchas stated, have resulted in a major change in the treatment of those with severe mental illness. In France, he observed, it was discovered almost by chance that a group of drugs called phenothiazines were effective in the treatment of many schizophrenics.

These antipsychotic drugs—such as thorazine, stelazine, melaril—are believed to block the brain's receptors for dopamine, stopping the relative excess of the neurotransmitter.

"They have been miraculous," said Barchas, "because prior to World War II, schizophrenia was a disease which almost inevitably resulted in a very bad outcome. Now an acute schizophrenic taking the medications will usually be markedly improved, and after a while will be finished with the treatment."

But this doesn't apply to all schizophrenia patients. Between 25 to 50 percent of the mentally disturbed patients get no help, or only temporary help in which they are improved but basically are still profoundly disturbed, he said. An analogous situation exists for depression. In both cases marked progress is being made.

But Barchas cautioned that such illnesses as schizophrenia and depression may have no single cause. The biochemical approach to finding out their cause is only one avenue. There is the psychological side, with attendant stresses and the psychological meaning of events; the social with family and interactional processes and role theory, as well as hereditary factors.

As part of the discussion of the psychiatry of the future, Barchas emphasized his view that ultimately there would be need for a new approach that would combine the advances in neurobiology with the behavioral approaches.

"We need to understand the ways in which behavior changes biochemistry and how the altered biochemistry in turn affects subsequent behavior," he stated. "Out of these concerns may come a new psychiatry perhaps requiring a different language to express those interrelationships which we can now only glean.

-more-

"A powerful early example of the need for multiple approaches is shown in the treatment of schizophrenia," he explained. "We are just learning that the best approach to treatment for many patients involves a combination of psychopharmacology with social and psychological approaches. That combination can be expected to be quite important in the future."

Scientists, Barchas said, are also interested in affective disorders such as mania and depression. His own laboratory, in collaboration with the Stanford Mental Health Clinical Research Center, is searching for biochemical bases of depression which is associated with several important neurotransmitters, such as serotonin and norephinephrine.

The two are distributed in varying concentrations throughout the brain, with the greatest concentration in nerve cells from areas thought to control emotion and mood.

"The most important biochemical theory of derpession," said Barchas, "states that it's associated with a deficit in serotonin or norephinephrine at critical synapses, the microscopic gaps between nerves cells."

Barchas said brain chemicals other than serotonin and norephinephrine may also be involved in depression. One group of these, called endorphins, has some actions similar to those of morphine and other opium derivatives.

"Since morphine can cause profound euphoria when injected intravenously and a state of great discomfort during withdrawal, it has been hypothesized that these morphine-like compounds are involved in depression," he said. Two scientists in the Pritzker Laboratory, Drs. Eckard Weber and Chris Evans, have found several new, previously unrecognized forms of endorphins and related substances.

"The finding of such substances is quite exciting," Barchas said. "We are at a phase of neurobiology similar to that of the finding of continents and islands. We know the finding of new neurotransmitters will be important for treatment and diagnosis in the future but do not yet know exactly what their significance will be or in what disorder they will prove important."

"The first demonstration that the endorphin-like substances in brain could be changed by stress was made by Dr. John Madden, then a predoctoral student at Stanford," Barchas said. Madden demonstrated that in certain types of stress the amounts of the endorphin-like materials are increased in the brain. At the same time there is a change in pain threshold. His findings may explain the oft-noted reports of soldiers in battle or of accident victims who suffer an injury but do not feel pain, he added.

In another Stanford study, Madden, now a member a of the Pritzker Laboratory, is working with Dr. Richard Thompson, professor of psychology. They are investigating the role of endorphins in certain types of learning, Barchas said. There is also evidence that endorphins may be important for a model of depression, the type referred to as learned helplessness.

"A great deal of work at Stanford and elsewhere is now underway to determine the role of endorphins in mormal metabolism and in psychiatric disorders," he added.

Science writers: Background information on topics covered in the Progress in Medicine lectures follows asterisks.

HERPES: RISKS, PREVENTION, AND TREATMENT

STANFORD—

Sexually transmitted herpes viruses, their risks, prevention, and promising treatments, will be the focus of a three-part "Progress in Medicine" lecture series, sponsored by Stanford University Medical Center, November 9, 16, and 23.

Each lecture is open to the public free of charge, and will take place at 7:30 p.m. in the Medical Center's Sherman Fairchild auditorium.

Thomas C. Merigan, Anne S. Yeager, and John Mills, three eminent researchers in infectious diseases, will describe recent advances in understanding and controlling two varieties of the herpes simplex virus, sources of cold sores and genital infections that afflict at least 15 million Americans, and their lesser known viral relative, cytomegalovirus (known as CMV).

As a part of the first lecture, Mills, a visiting scholar at Stanford from the University of California, San Francisco, will discuss his studies of the role CMV plays in a mysterious crippler of the immune system that has killed hundreds in the last year in an epidemic that stretches across the continent. Labeled "acquired immune deficiency syndrome" (AIDS), the disease seems particularly prevalent in male homosexual communities, for reasons still unclear to researchers.

Yeager, associate professor of pediatrics at Stanford, will describe herpes' effects on young children in her presentation November 16 entitled "Risks for fetuses and infants in contact with infected adults." Both herpes simplex and CMV can be deadly for the fetus and newborn, whose immune systems are still underdeveloped.Yeager was instrumental in developing a test for CMV in transfused blood. Use of the test to screen all blood given to newborns at Stanford has nearly eliminated the threat to these patients.

Merigan, Becker professor of Medicine and a leader in Stanford's research of the anti-viral compound interferon, will discuss "Present and future methods of prevention and treatment" of herpes on November 23.

-more-

2-2-2

In addition to testing ways to prevent a dangerous CMV infection in immune suppressed patients, Merigan and colleagues are testing antiviral drugs such as leukocyte interferon and adenine arabnoside to halt the infection once it starts.

Seats for each lecture will be made available on a first come, first served basis, so early arrival is recommended.

Those interested in further information or registration forms can call the Medical Center's office of public events at 497-6389.

* * * * *

A usually innocuous virus contracted by 40 percent of all Americans sometime during their lifetime, CMV has been found to suppress the immune system in laboratory animals and some humans, and to convert normal cells to cancerous ones in test tube cultures. CMV is also known to cause severe disease in recipients of organ transplants who are given drugs that suppress their immune systems.

In collaboration with the bone marrow transplant program at the University of California, Los Angeles, Merigan recently gave transplant patients blood plasma containing high concentrations of anti-CMV antibodies. (Because of the strong radiation treatments the transplant candidates must undergo, their immune systems are extremely suppressed and their risk of contracting CMV is high.)

Results of the study, published in the July 8 *Annals of Internal Medicine*, showed that while the CMV infection itself was not prevented by the antibody boost, dangerous complications of the infection, such as pneumonia, hepatitis, and encephalitis were significantly reduced.

The researchers currently are repeating the experiment with a modification: instead of giving the antibody as a component of plasma, which can only be given in small, limited quantities, they are now injecting the patients with pure antibody, in hopes of maximizing the therapeutic effect.

As yet, no long lasting, effective treatment exists for the herpes viruses, Merigan said, though several promising drugs have been made available recently for testing.

"These are the first drugs that seem active against these infections and I think we'll see them widely studied in the next few years," he said. "There are other drugs coming up which will be even more effective, judging from the first experiments in animals. I'm not saying these will cure the infection," Merigan cautioned. "The real challenge for the future will be total prevention of the infection. We need further understanding of the disease mechanisms in order to pinpoint factors that cause their occurence."

The following release is being issued jointly by Stanford University Medical Center and Children's Hospital at Stanford.

HOSPITALS SIGN CONSOLIDATION AGREEMENT

STANFORD—

A formal agreement consolidating Children's Hospital at Stanford (CHAS) and the pediatric facilities of Stanford University Hospital (SUH) was signed Thursday night (Nov. 4) at ceremonies attended by the new organization's recently chosen board of directors.

"Just like a marriage courtship, we have spent the past year getting to know each other's needs and expectations, and we are now joyously celebrating a bonding of our goals and interests," said Lawrence G. Crowley, chairman of the new 10-member board and President of SUH.

"And like a marriage, we must marshal the groundwork and bond thus far achieved to forge an ongoing relationship," added Crowley, who also serves as vice president for Medical Affairs at Stanford University.

"We will now get on with the business of taking two dynamic institutions and creating a new entity which is even greater than the sum of its individual parts," said Kenneth H. Sayre, of Menlo Park, chairman of the original CHAS board and member of the new CHAS board which will now guide the consolidation through final planning and construction. The $40 million hospital is to be a separate building physically attached to SUH and ready for occupancy by a target date of May 1987.

The formal contract was signed by Sayre and Crowley, representing the two hospitals, and by Donald Kennedy, president of Stanford University, which operates SUH as a wholly-owned subsidiary. The agreement creates a new corporation to operate the consolidated children's medical center and mandates the new board to begin planning for construction and other details.

Five of the new CHAS board members were selected by and from SUH's board, while five others were chosen from CHAS' current board, which will continue to operate the existing hospital until it is moved to the new facility. The existing CHAS and SUH boards will serve as the parent governing bodies of new CHAS, Crowley and Sayre said.

Members of the new board from CHAS include Charles A. Anderson, Menlo Park, formerly chief executive officer of SRI International; Birt Harvey, a Palo Alto pediatrician; Shirley Oneal, San Jose, president of the CHAS association of hospital auxiliaries; Lucile Packard, Los Altos Hills, vice chairman of the current CHAS board; and Sayre, a vice president of Kidder, Peabody and Co., San Francisco.

-more-

SUH's members include, in addition to Crowley, Conrad F. Gullixson, a Palo Alto attorney, former city councilman and past president of SUH's board; Linda Meier, Atherton, an active Stanford alumna and community leader; Dominick P. Purpura, dean of the Stanford University Medical School; and Frank Roberts, senior partner with the San Francisco law firm of Pillsbury, Madison and Sutro and former SUH board president. Meier and Roberts had also served on the old CHAS board until they resigned last month to be among SUH's appointees to the new CHAS board.

In addition to regular members, each originating board appointed two alternates.

CHAS' alternates are Mary Elizabeth Kendrick, of Atherton, a community leader; and Lawrence R. McDonnell, of Palo Alto, retired vice president of public information for Pacific Gas and Electric Co.

SUH appointed William F. Massy, Stanford's vice president for business and finance; and David J. Stone, a Palo Alto businessman.

The contract approved during Thursday's ceremony stipulates that Crowley, as vice president for medical affairs, will serve as ex officio chairman until the new hospital is occupied.

Most provisions of the contract were announced in July when both parent boards signed an agreement in principle to consolidate.

Formal planning for a single children's medical center was begun by both boards in November 1981, but informal discussions have been occurring for many years. Central issues included rising costs, concerns about duplication of services, as well as trends in pediatric care, which resulted in attracting to Stanford the more difficult-to-treat cases and the need for a comprehensive approach to the care of children.

About 2,500 patients yearly must be shuttled one mile across a busy thoroughfare between the hospitals for specialized treatment at SUH.

The new facility will consolidate the 60 beds of CHAS and the 44 pediatric acute medical-surgical and pediatric intensive care beds of SUH. The new facility also will house the Stanford-Children's Ambulatory Care Center, which provides 27 separate clinic services, including such specialties as cardiology, birth defects, oncology and child psychiatry.

The new children's medical center will continue to provide inpatient services in the 15 specialties now offered by both hospitals.

The existing CHAS facility at 520 Willow Road in Palo Alto will continue to operate until the new building is completed. The consolidation must now pass through the review process of state and local agencies.

EIGHTH HEART-LUNG PATIENT REPORTED STABLE

STANFORD—

A 40-year-old Ventura, Calif. man was reported in stable condition Monday, three days after he became Stanford University Medical Center's eighth heart-lung transplant recipient.

Medical personnel said Monday Ronald Grunden was progressing well and has been able to sit in a chair and take some medications orally.

On Friday, Grunden was reported in critical condition, the standard designation for patients who have just completed the double transplant.

The five-hour operation was performed by Dr. Stuart Jamieson, assistant professor of cardiovascular surgery, and five physician colleagues on the transplant team.

"While the most important period is still to come, we are optimistic that Mr. Grunden will return to an active and productive life in the coming months," said Jamieson, who directs the heart-lung program.

The double transplant was the first performed at Stanford in nearly five months, although four candidates have been waiting for donors.

"This procedure benefits a select group of patients who otherwise would die within months," said Jamieson.

"Our greatest difficulty is the limited supply of donors which makes this operation a reality for only a very small number of people. Several potential recipients have died in the last few months for lack of donors."

But Jamieson said more operations could be performed if more individuals would make their intentions to donate their organs clear to their families or sign donor statements on their driver's licenses.

Several potential recipients are always waiting, since the recipients and donors must be matched by size and also by blood type and tissue type to reduce the impact of rejection, the body's natural tendency to fight off foreign tissue.

-more-

Grunden suffered from a congenital abnormality of the heart called a ventricular septal defect (VSD). A hole present from birth allowed blood to flow between the chambers of the heart, causing a volume overload of blood in the lungs.

This overcirculation causes pressure to increase in the pulmonary arteries that the right ventricle of the heart is unable to overcome.

Therefore, both the heart and lung become damaged over many years, leaving a heart-lung transplant as the only viable alternative to death.

VSD usually can be corrected in small children by surgery, but the operation was not available in Grunden's youth.

Despite a slowly deteriorating condition, Grunden was able to work as a computer technician and typesetter until February 1980.

Stanford performed its first heart-lung transplant surgery on March 9, 1981, on 45-year-old Mary Gohlke of Phoenix, Ariz., after researchers at Stanford had tested a new drug which was effective at fighting rejection, while allowing the windpipe to heal and much of the body's natural defense mechanism against infection to remain intact.

The new drug is cyclosporine, a fungal derivative, which until a few month ago was known as Cyclosporin A. The Food and Drug Administration ordered the change, contending the first name was too similar to another class of drugs and might be confusing.

Early attempts at heart-lung transplantation between 1968 and 1971 in Texas, New York, and South Africa, resulted in a survival rate of no longer than 23 days.

Four of the first seven Stanford transplant patients have returned to active lives, including Gohlke, who has gone back to a career in newspaper advertising. Two of the patients died of complications encountered because of previous surgeries, while a third died nearly a month after her operation as a result of kidney failure, attributed at least in part to exhaustion rendered by a five-year battle against pulmonary hypertension.

'RIGHT TO DIE' TOPIC OF TV SHOW FEATURING STANFORD UNIVERSITY MEDICAL CENTER PHYSICIAN, CHAPLAIN

Case: A 25-year-old man lies comatose in an intensive care unit of a hospital after being critically injured in a car accident. Not only will he never be able to resume his formerly active lifestyle, but his basic life functions are being sustained only with the aid of machines.

Dilemma: Should the man be kept on life support systems indefinitely, or should he be taken off them and allowed to die?

With the advent of modern medical technology and intensive care units, the question of the right to die is coming up more frequently. Stanford University Medical Center's Dr. Thomas A. Raffin, director of respiratory therapy and asistant chief of medicine; Dr. Ernle Young, chaplain; and Attorney Morris Abram, chairman of the President's Council on Bioethics discuss this topic on the Nov. 25 segment of "Over Easy", a Public Broadcasting System talk show. It will be aired at 7:00 pm, and again on Nov. 26 at noon.

"If a patient is on life support systems, we go by these guidelines: cause him no harm, restore him to health, and relieve suffering," Raffin said. "Our goals are either to save the patient and restore the salvagable functions, or to help him die a dignified death."

Young added what he believes should be another guideline: patient autonomy. "The patient should be able to determine what he'd like the quality of his life to be," he said.

"Technology has accelerated, but the ability to handle the technology at a moral level has often lagged behind," he added.

Often, he explained, family members are torn between the emotion of wanting to keep their relative alive, regardless of his condition, and the practicality of doing what is medically, humanely, and financially the best option. Reaching these decisions often causes conflicts between family members, and physicians. Chaplains, social workers, and other trained professionals are especially helpful in these circumstances, all three guests agreed.

One way to avoid forcing family members to make these decisions, they advocated, is for individuals to discuss the options with family members in advance. Individuals can also sign a "living will," available through the Society For The Right To Die. "The document is not legal, but it does express the person's wishes," Young said.

"Over Easy" is a national daily, half-hour talk show. In its sixth season, it is aired locally on KQED, San Francisco. Hosts Mary Martin and Jim Hartz feature guests who are authorities in subjects pertinent to growing, changing adults.

NEW PSYCHIATRY FACILITY BILLED AS UNIQUE IN WESTERN U.S.

STANFORD—

A new facility for neurochemical research has been dedicated at the Stanford University School of Medicine.

The new facility, established as part of the Nancy Pritzker Laboratory of Behavioral Neurochemistry, was dedicated to the memory of Jack D. and Sophie A. Pasarow, parents of the major donor to the project.

The new Pasarow Analytical Neurochemistry Facility has equipment and expertise which are unique in the western United States, said Dr. Jack Barchas, director of the Nancy Pritzker Laboratory.

The dedication ceremony launched the new facility and thanked the donors who made a fund drive for the refurbishing and remodeling of the Nancy Pritzker Laboratory successful.

According to Barchas, the Pasarow Facility is intended to support neurochemical research, which requires the detection and measurement of neurotransmitters—chemicals that transmit information from one nerve cell to another. For this purpose the facility has equipment which can identify substances present in minute amounts and which will aid studies in severe mental disorders in adults and children. The equipment includes a new top of the line Hewlett Packard mass spectrometer.

Dr. Dominick Purpura, dean of the Medical School, said that recent developments in psychiatry are permitting the field to move with effectiveness toward an understanding of the critical problems of mental illness which affect millions of people.

The Pasarow Facility comprises one of five divisions of the Nancy Pritzker Laboratory. The others are peptide chemistry, biochemical neuroanatomy, biochemical regulation, and behavioral neurochemistry.

The remodeling and refurbishing of the Nancy Pritzker Laboratory and the establishment of its Pasarow Facility were made possible by a combination of private donors, private foundations, and government sources. Besides Claire and Robert J. Pasarow of Southern California, other private donors included: Moshe and Margaret Alafi of Berkeley, Bill and Diane Bridgford of Fullerton, John and Marjorie Hines of Chicago, Peggy and Albert Orschel of Chicago, Peter and Barbara Pande of Palo Alto, Al and Edie Shansky of Hillsborough, and Garland and Pauline Sinow of Long Beach.

-more-

"We are deeply appreciative of the gracious help and key role the donors had in providing for this important research unit," stated Barchas.

The ceremony took place five years after the opening of the Nancy Pritzker Laboratory, established with a gift from the Pritzker Foundation. Several foundations including the Grant, MacArthur, McGraw, Norris, and Pritzker, were important in the current remodeling and refurbishing effort.

In addition, government support was received from the National Institute of Mental Health and the Office of Naval Research. "Individuals, foundations, and government are all important in research on mental illness, where there has been so little tradition of support," noted Barchas, Nancy Friend Pritzker Professor and associate chairman of psychiatry. "Each sector performed a needed role in this three-year $1,000,000 fund drive."

Dr. Kym Faull, senior research associate in psychiatry, will head the Pasarow Facility. Said Barchas, "Dr. Faull is one of the leading experts in this country on the application of mass spectrometry to the analysis of neurotransmitters and their metabolites."

"We are delighted to be in the remodeled space," he concluded, "and the work is already going full speed ahead."

HOSPITAL WORKERS VOTE AGAINST JOINING UNION

STANFORD—

Service and maintenance workers at Stanford University Hospital have voted against representation by Local 715 of the Service Employees International Union AFL-CIO.

The final tally Saturday night showed a vote of 778 against, 253 in favor, with 22 ballots void or challenged. Approximately 1,150 employees were eligible to vote, showing about a 90 percent turnout during National Labor Relations Board voting Friday and Saturday.

"We are very pleased with the results," said Dan Robinson, SUH assistant director of personnel and manager of labor relations. "We feel that it is a strong vote of confidence. We will continue to live up to this very strong vote of confidence which our fellow workers have shown."

An NLRB representative said the election would be certified after 10 days unless either the employer or the union filed objections.

Michael Baratz, executive secretary of Local 715, said after the election he was unsure whether the group will file objections to the results.

Workers eligible to vote included a variety of job categories, including nursing assistants, unit service assistants, housekeeping and dietary workers and maintenance employees.

No employees currently are represented by Local 715 at the hospital, a wholly-owned non-profit subsidiary corporation of Stanford University.

A nonaffiliated union, the Committee for the Recognition of Nursing Achievement (CRONA), represents about 1,250 registered nurses and is the only union currently representing employees at the hospital.

At the university, a Local 715 contract covers a bargaining unit of 1,350 workers.

STANFORD COMMUNITY OF INTERNISTS SPONSOR ONE DAY SYMPOSIUM

STANFORD—

Stanford Community of Internists (SCI) is sponsoring a one day symposium featuring Lloyd H. Smith, Jr., M.D., professor and chairman of the Department of Medicine at University of California, San Francisco on Nov. 18.

Smith is scheduled to present the Grand Rounds lecture—"Pathogenesis and Treatment of Gout"—in Fairchild Auditorium at 8:30 a.m.

He will also lead a lunchtime conference with housestaff and students on "Urolithiasis". The public is welcome at both events.

A dinner is scheduled for members of SCI later that evening, at which Smith will lead an informal discussion on "Reflections of Academic Medicine".

Smith is also physician-in-chief of the Medical Service at University of California Hospitals, San Francisco. He has been a visiting professor at University of Geneva (Switzerland), Pahlavi University (Iran), University of Sydney, and University of Auckland (Australia). He serves on numerous professional and editorial boards, and is the author of at least six books and 89 journal articles.

SCI, formed in 1979, is an organization of community and Stanford University Medical School faculty internists. With about 135 members, the group sponsors a number of educational events each year. For further information, call Sally Mixer at 497-5454.

'TWIXT NERVE AND MUSCLE: CAUSES, TREATMENTS OF MYASTHENIA GRAVIS HIGHLIGHTED IN UPCOMING LECTURE

STANFORD—

Daniel Drachman, a renowned researcher in the causes of the neuromuscular disease "myasthenia gravis," will address Stanford community members next week in the first annual lecture of a series on the causes and treatments for the disease. The lectureship is sponsored by the department of neurology with a grant from the H. S. Kittredge Research Fund.

Open to the public, the presentation will be held in room M104 of the Stanford University Medical School at 5:00 p.m. on Thursday, November 18.

Double vision, weakness that gets worse as the day wears on, and sometimes fatal paralysis are symptoms of the disorder that effects between five and ten thousand persons in the United States each year. The disease seems to stem from malfunctions in an overzealous immune system at neuromuscular junctions, places in the body where nerve and muscle meet.

Drachman, a professor of neurology at Johns Hopkins University in Baltimore, Maryland, has been a leader in understanding the disease for the last fifteen years, according to Lawrence Steinman, assistant professor of neurology at Stanford.

"It was Drachman who really showed how the receptor for acetylcholine (a chemical messenger at the nerve junction) was involved in the development of myasthenia gravis," Steinman said. "He showed that when antibody binds to the receptor, the receptor is shed and you lose the ability of the muscle to respond to the nerve impulse."

Florence and H.S. Kittredge, long-time residents of the Santa Clara Valley, donated, "a generous grant" to Stanford University Medical Center in 1972 for studies of the causes, treatments, and potential cures for myasthenia gravis, Steinman said. A portion of the grant was set aside in 1982 to fund the neurology lectureship which is scheduled to bring to Stanford each year "people of national and international reputations who are making direct contributions to clinical treatments of the disease."

ELDERLY ATHLETES NEEDED

STANFORD—

About 30 active, healthy, male volunteers over 60 are needed to participate in a study at Stanford University Medical School on the relationship between metabolism and physical conditioning.

Dr. Mark Rosenthal of the Division of Gerontology has been researching glucose metabolism in the elderly. His findings, published in last month's issue of the *Journal of the American Geriatric Society,* indicate that the so-called "glucose intolerance of the elderly" happens only in certain individuals.

"While other researchers claim that poorer handling of glucose is inevitable in aging, I found that some 80-year-old subjects had perfectly normal glucose tolerance and were better than normal in their sensitivity to insulin," he stated.

Rosenthal has theorized that physical fitness is one factor that might explain his observations, that perhaps "staying in good shape" prevents any deterioration of glucose metabolism, or promotes normal handling of glucose.

Rosenthal recently observed a correlation between insulin sensitivity and physical fitness as measured by maximal exercise testing in subjects up to age 50. Now he wants to extend the study to a group of older men.

Athletes currently in training are preferred for the study, which requires spending two nights and two mornings in the clinical research center (CRC) at Stanford. Rosenthal will compare well conditioned elderly athletes—mostly runners and swimmers—with more sedentary men of the same age group.

Participants will undergo, at no cost to themselves, glucose tolerance testing, testing for insulin sensitivity, and basic lab tests. Medical histories will be taken and complete physicals including EKG performed.

As outpatients, volunteers will go through exercise testing on a bicycle ergometer at the Stanford Heart Disease Prevention Program. Also, percentage of body fat will be measured by underwater weighing.

Rosenthal has already tested eight subjects, and expects the study to last until spring. For further information, contact him from 9-5 weekdays at 858-3933.

NINTH HEART-LUNG TRANSPLANT PERFORMED AT STANFORD; EIGHTH DOING WELL

Editors: The following release was sent out Tuesday p.m. via Business Wire:

STANFORD—

Philip McGrath, who doctors said faced death within a few months, became the second heart-lung transplant patient at Stanford within four days.

The 22-year-old Islip, N.Y., man was reported in critical but stable condition following the five-hour operation performed Tuesday by Dr. Stuart Jamieson and five colleagues from the Department of Cardiovascular Surgery.

The operation was the ninth heart-lung procedure performed since Stanford began the program in March 1980.

Jamieson said the transplant was performed without complications, offering the former college student a potential reprieve from the death sentence imposed by his condition, known as a ventricular septal defect (VSD).

The abnormality was the same which led to last Friday's heart-lung transplant for Ronald Grunden, 40, of Ventura, Calif.

Jamieson said Grunden was making excellent progress and has been able to sit up in a chair and eat solid foods. He was listed in satisfactory condition Tuesday.

"I think we have been able to offer both Mr. McGrath and Mr. Grunden at least a fighting chance for productive lives," said Jamieson, an assistant professor of cardiovascular surgery who directs the heart-lung transplant program.

Both McGrath and Grunden previously had led active lives as long as their conditions permitted. McGrath had attended Suffolk Community College on his native Long Island until September 1980, when he withdrew for medical reasons. Grunden had worked for a Southern California newspaper as a computer technician and typesetter until ill health forced him to leave in February 1980.

VSD sufferers are born with a hole between the left and right chambers of their heart. Surgeons currently can correct the hole in infants, but that procedure was unavailable to McGrath and Grunden.

When left uncorrected, the hole allows blood to flow between the chambers of the heart, causing too much blood to enter the blood vessels in the lungs.

The overcirculation causes pressure to increase in the pulmonary arteries that the right ventricle of the heart is unable to overcome.

Therefore, both the heart and lungs become damaged over many years, and a heart-lung transplant becomes the only viable alternative to death.

-more-

VSD is one of two common conditions which currently is correctable only by the double transplant operation. The other condition is pulmonary hypertension, in which the blood vessels in the lungs constrict for reasons not yet learned. In this condition, blood cannot flow effectively through the lungs, creating a backlog which ultimately damages the heart.

Since the recipients and donors must be matched by size and also by blood type and tissue type, three recipients at Stanford currently are waiting, ensuring that if a heart and lungs become available, a matching recipient will be ready.

"There are literally hundreds of people who could benefit from thi operation, but the difficulty in obtaining donors has meant nearly all of these will die before any real chance of surgery," Jamieson said. The doctor added that Stanford physically could only accommodate 12 heart-lung transplants a year, but if donors were available they might be accommodated elsewhere.

Although Jamieson said he was pleased with the initial outcome of the two latest transplants, he cautioned that recuperation will be a lifelong process.

Although several of the nine heart-lung transplants, and many of the 244 heart-only transplants performed at Stanford have returned to active, even athletic lives, they must take medication for the rest of their lives to minimize the impact of rejection, the body's natural tendency to fight off foreign tissue.

The discovery of Cyclosporine (formerly called Cyclosporin A) was the impetus that allowed the heart-lung procedure to be revived last year after an 11-year hiatus.

The new drug overcomes problems which caused the three earlier attempts in New York, South Africa, and Texas, to result in failure. Cyclosporine, used on both heart and heart-lung transplant patients at Stanford since December 1980, is more effective than older immunosuppressives at fighting rejection while minimizing the possibility of infection. But more importantly, it allows the windpipe to heal and the lungs to function.

Four of the first seven Stanford transplant patients have returned to active lives. For example, the first Stanford heart-lung transplant, Mary Gohlke, 45, Phoenix, Ariz., has returned to a career in newspaper advertising.

Three of the patients died, all within a month of their surgeries. Doctors said two patients died of complications encountered because of previous heart surgeries, while another death was attributed to kidney failure, resulting at least in part to exhaustion rendered by a five-year battle against pulmonary hypertension.

STANFORD UNIVERSITY HOSPITAL DEDICATES NEW CHAPEL

STANFORD—

The dedication ceremony for Stanford University Hospital's new chapel is scheduled for 4 p.m. Nov. 17, culminating an open house scheduled to begin at 2 p.m.

Located across from the hospital gift shop, the new facility is being completed just about a year after the former chapel was eliminated as part of patient admitting services' renovation.

The chapel features a floor-to-ceiling stained glass window, created by artist Ginny McAfee. The window symbolizes "hope in the midst of pain and despair," said Dr. Ernle Young, chaplain. It contains no sectarian elements, he added, to maintain the hospital's nondenominational policy. The window is bordered by tiles from the University's original Memorial Chapel, which was rebuilt after the 1906 earthquake.

"The chapel has really been missed," Young said. "Staff as well as families and patients need a quiet place available to them."

Young, who organized the chaplaincy at SUH 10 years ago, said he and his colleagues, Reverend Frank Geer and Father John Hester, serve those who seek them out by simply responding to their needs—ranging from finding accomodations at a local hotel or buying an airline ticket, to carrying out religious functions or just listening to people express their feelings.

"The most challanging function for me is to deal with people's existential questions about life and pain, and helping them find satisfactory answers," Young said.

About 65 percent of the patients Young deals with are critically or terminally ill and are concerned with issues such as the right to die and the quality of life. In such cases, Young said he tries to present all options to families and patients, and help them decide what may be the best for all involved.

Young said he encourages local clergy to continue caring for their congregation members while they are in the hospital. "Our offices serve as a base for clergy. We don't want to come in between them and their members, but rather we are here to supplement their services."

The chaplains' offices are located in C112A, next door to the new chapel, and they can be reached at 497-5101. The chaplains are there during regular business hours, and are always on-call.

HERPES SIMPLEX: TRIMMING FICTION FROM FACTS

STANFORD—

Despite a "herpes hysteria" arising from increasing media coverage of the sexually transmitted virus, the disease is probably not as infectious as most people believe, said John Mills, a visiting scholar in infectious diseases from University of California, San Francisco.

Mills spoke Tuesday night in an overview lecture on the clinical problems with herpes simplex viruses in adults, in the first of a three-part series of public talks on the viruses.

"Herpes, both in the perception of the physician and the lay public is, at the present time, a fairly serious problem," Mills said. "What is not clear is whether there has been a real increase in the incidence of this disease in recent years."

Though Mills cited one study that showed a nearly ten-fold increase in the reporting of herpes simplex outbreaks between the years 1966 and 1980, he said the jump could be simply a result of the public's increasing awareness of the disease and willingness to report symptoms to physicians.

The two herpes simplex viruses that afflict at least 15 million Americans with recurrent cold sores and genital infections stem from a family of viruses that include those causing chicken pox, shingles, and mononucleosis.

Currently there is no cure for herpes simplex infection. Though outbreaks of the open sores symptomatic of the infection usually last less than a week or two, and may occur only once or as often as several times a year, the virus remains in the body as long as the person lives, and can become active at any time without warning.

Nearly 90 percent of all Americans have antibodies to herpes simplex virus I (HSV-I), indicating that sometime during their life they were exposed to the infection, according to a recent study. Usually associated with milder, less frequent outbreaks of blisters than HSV-II, HSV-I most often causes sores in and around the mouth (though genital infections are possible), and can be contracted simply through contact with an infected person's saliva, Mills said.

-more-

HSV-II, the virus most often associated with genital inflamation, occurs less frequently—in between one and ten percent of all Americans—the same study showed. Current commercially available blood tests don't distinguish between HSV-I and HSV-II, so patients may learn they have contracted herpes, but not know which variety they have.

Immunologic tests and probes using monoclonal antibodies can accurately identify each virus strain, and should be ready to move from the laboratory to the physician's office within three or four years, said Mills, who is chief of infectious diseases at San Francisco General Hospital.

Despite its reputation, HSV-II "is not terribly infectious," Mills told the crowd. "Everybody worries a bit about getting the infection from a toilet seat or towel, but it takes sexual contact or the equivalent for transmission of the virus."

Because herpes has a thin protein coat that dries out easily, the virus can't survive more than 24 hours out: ? the body and has a tough time infecting healthy, unbroken skin. "Skin-to-skin or mucous-to-mucous contact is required for infection," Mills said.

People with herpes frequently ask whether they can inadvertently transmit the infection to a sexual partner during the disease's dormant periods. The answer is a qualified no, according to Mills. "You probably don't get herpes from people who are completely asymptomatic," the scientist said, "but because symptoms can be mild most individuals don't realize they have the disease."

"Barrier" birth control methods such as condoms, and "open, empathetic communication between sexual partners" can help minimize the risk of infection, Mills said.

Dentists, anesthesiologists, and other health professionals who work in patients' mouths should wear rubber gloves, he said, to avoid contracting the oral form of the virus.

While herpes is bothersome but not life-threatening for the great majority of adult sufferers, the infection can be fatal in newborns. Anne S. Yeager, associate professor of pediatrics at Stanford, will describe the "risks for fetuses and infants in contact with infected adults" in the second lecture of the series on November 16.

Thomas C. Merigan, professor of medicine in infectious disease will profile current and future treatments for the disease in the final lecture on November 23. Both presentations will be held at 7:30 p.m. in the Medical School's Sherman Fairchild auditorium.

(ADVANCE) FOR PM RELEASE MONDAY, NOVEMBER 15, 1982

COMPUTERS TO CUT COSTS OF CLINICAL TRIALS, CARDIOLOGIST SAYS

STANFORD—

Because of advanced technologies, such as computerized image processing, doctors can now study heart disease in new types of less costly clinical trials, according to the president of the American Heart Association.

"Such studies could utilize a few hundreds of volunteers instead of the many thousands demanded by most of today's large scale clinical trials," said Dr. Donald C. Harrison, Irwin Professor of Medicine and chief of the Division of Cardiology at the Stanford University School of Medicine.

"The duration of such studies would only be a few years, the costs would be acceptable and therapeutic interventions would be rigorous," he said.

The new type of clinical trial would evolve a new strategy to study the factors which result in progression and hopefully regression of atherosclerosis, or hardening of the arteries, Harrison said. Physicians would visualize the development of atherosclerosis by computer-based techniques, so that treatment may begin at earlier stages of the disease.

"Such techniques have been already developed for studies of femoral and coronary arteries," he said.

Harrison addressed the annual meeting of the American Heart Association in Dallas, Texas, Monday (Nov. 15).

Clinical trials that compare prospectively the effects and value of a given treatment against a control in human patients have long been regarded as the cornerstone of modern clinical medicine.

They include the so-called "therapeutic trial" in which doctors document statistically one treatment as being superior to another, and the "intervention trial" which determines the probable effect of a treatment on the biological processes of man.

Clinical studies have been utilized with an increasing scientific basis and sophistication, and more of them have been performed in the past 20 years than in all of recorded medical history, Harrison said. Yet there's more controversy about them than in any previous time.

-more-

Harrison cited these reasons:

- clinical trials require long-term commitments for study and are expensive.
- they compete for research dollars for basic and clinical research of many institutions.
- they fail to provide answers, and they become self-perpetuating in that one trial uncovers multiple other questions requiring more clinical trials.

"This results in massive costs," Harrison said.

He cited a recently federally-funded study on the value of trying to diminish the major risks associated with heart disease that cost $115 million. The study found no significant difference in deaths between a group that received special medical treatment and one that received more ordinary care.

"Results may be influenced by multiple uncontrollable factors, especially in field trials in free-ranging populations," Harrison said. "Control populations modify their behaviors with societal changes and thus confuse the results. This clearly occurred in the multiple risk factor study."

In addition, Harrison said, not everyone agrees with trial design. Some are timed poorly after the questions they seek have already been answered by ordinary clinical practice. And there are moral and ethical limits to clinical trials.

"These controversies," Harrison said, "suggest that we need to examine ways to improve clinical trials in the future."

Harrison described an example of a model computer analysis system that he developed with his colleagues, Dr. Edwin Alderman and William Sanders, for studying coronary arteries.

The system provides direct visualization of the extent of atherosclerosis in arteries so that treatments may be applied at earlier stages of the disease.

The computer is programmed to provide volumes, diameters, areas and degree of narrowing of multiple segments of the vessel. These variability limits are used to set boundaries and quantify vessel changes in atherosclerosis.

"The value of this technology is that it provides a continuous variable measure, from small lesions to large ones," Harrison said. "Every participant in the study contributes a value rather than a small percent of patients having death or infarction (heart attack) as occurs in regular clinical trials."

Numerous technologies now available will permit new horizons for clinical trials in the next two decades, he predicted, and "we should use them."

GUEST LECTURER TO SPEAK ON OBESITY

STANFORD—

"Obesity: Why the Losing Battle?" is the topic of the tenth annual Katharine D. McCormick Distinguished Lecture to be held at Stanford Medical Center 5 p.m. Thursday, Nov. 18.

The speaker, Dr. Judith Rodin, is a leader and respected investigator in the field of behavioral medicine. She is presently a professor of psychology and psychiatry at Yale University.

Rodin's approach to the problem of obesity has been largely responsible for current methods of treating and understanding this major medical problem. Using rigorous methodology, she demonstrated the importance of behavior in understanding the pathophysiology of obesity.

Recently Rodin studied aging using similar methods and showed dramatic effects on the aged when behavioral interventions were introduced.

Rodin's most recent honor is election to the Institute of Medicine of the National Academy of Sciences. She has served on a variety of editorial boards and professional societies, been the recipient of numerous honors and professional recognitions, and published widely.

Rodin graduated from the University of Pennsylvania in 1966, received her Ph.D. from Columbia University in 1970, and continued her education as a postdoctoral fellow at the University of California, Irvine, in 1971. She joined the faculty of New York University in 1970, and transferred to Yale in 1972.

The McCormick Lectureship honors Katharine Dexter McCormick, who donated $5 million to Stanford Medical School in 1969 with the expressed wish that it be used "for the encouragement and assistance of women pursuing the study of medicine, in teaching medicine and in engaging in medical research."

Katharine McCormick was a co-founder of the League of Women Voters and a vigorous champion of women's rights.

Previous McCormick speakers at Stanford include Drs. Marian Koshland, Maria New, Rose Payne, Rita Levi-Montalcini, Elizabeth Hay, Barbara Korsch, Rosalyn Yalow, Helen Ranney, and Mary Ellen Avery.

Rodin's lecture will be open to the public though specifically addressed to the medical community. (Continuing medical education credit is available.) The presentation will take place in the Fairchild Auditorium, with a reception in the lobby to follow. For further information call 497-6038.

HOFFMAN NAMED HARTFORD FELLOW

STANFORD—

Dr. Brian Hoffman, assistant professor of medicine, has been named one of twelve 1983 John A. and George L. Hartford Fellows by the Harford Foundation in New York City.

Each Fellow will receive $105,000 over a three-year period as support for the early stages of his medical research career, as well as a stipend paid to the sponsoring institution for research expenses. Each Fellow is a young physician beginning on a faculty track in a U.S. medical school who plans to pursue a career in medical research.

Hoffman is interested in the mechanisms by which catecholamines, such as adrenalin, activate cells. He is particularly interested in the inhibition of the enzyme adenylate cyclase. His fellowship support will begin in July, 1983.

The 1983 Hartford Fellows are the fourth class of Fellows to be supported by the Hartford Foundation since the program was established in 1979. The objective of the program is to encourage promising and highly qualified young physicians to pursue medical research careers.

Twelve Fellows are selected annually through a national competition. This year, 94 individuals were nominated by 62 American medical and research institutions. The Fellows were selected by an advisory committee of prominent medical researchers.

In addition to the Fellowship program, The John A. Hartford Foundation makes grants to stimulate health care payment system reform and to promote efficient energy use. In 1981, the Foundation gave more than $10 million to projects in these three areas.

HOLISTIC HEALTH TOPIC OF NURSES' CONVENTION

STANFORD—

The public is invited to attend "The Nurse as Healer: Self and Others," a program planned for the 1982 CRONA (Committee for the Recognition of Nursing Achievement) Convention, to be held Nov. 22 and 23 in the Fairchild Auditorium.

Topics of the first day will center on holistic health, with continuing education credit available. Speakers Joyce Lechuga and Katharine Riordan will address such issues as "Disease, Holistic Health and Personal Responsibility," "Concept of Stress/Message and Benefits of Illness," "Mind/Body Relationship in Creating Illness and Health," "Role of Nutrition in Health Treatment for Healthy, Vital Nurses," and "Experiential Visualization in Healing."

The registration deadline is Nov. 18 for both days' programs and Monday's banquet dinner at Rick's Swiss Chalet in Palo Alto, which will include a discussion by Bonnie Berg of "Women's Health from a Holistic Perspective." Fees will be charged for that day.

Tuesday will consist of the CRONA business meeting, including a talk by President Hedy Dumpel on "CRONA's Art of Collective Bargaining," as well as discussion of bylaws, resolutions, and budget. Attendance at the business meeting is mandatory for area representatives.

For further information call the CRONA office in Palo Alto at 325-2801.

STANFORD UNIVERSITY MEDICAL SCHOOL SPONSORS ACADEMIC EXCHANGE BETWEEN AMERICA, ASIA

STANFORD—

A program promoting the exchange of medical education and research between Asia and America has been established by Stanford University School of Medicine's Department of Medicine, according to Dr. Thomas Raffin, assistant chief of the department.

Stanford University-Asia Medical Fund (SAMFUND) will sponsor the exchange of research fellows, and eventually faculty and educational and research programs between universities in Asia and Stanford, he said. The first group of up to four fellows is expected to arrive at Stanford for the 1983-84 school year for up to a three-year stay.

"The purpose of this funding is to improve health care and increase communication and understanding," Raffin said. "By bringing together people from the Pacific Basin and America to compare and exchange ideas, a framework will be established for learning, understanding, and growth."

Specifically, Raffin said, the fellows will "work in some of Stanford's top investigative laboratories. They can then take their newfound knowledge and expertise back to their own universities and continue developing their own careers."

In turn, he continued, "there is exciting opportunity for Stanford fellows and faculty to spend time at Asian universities investigating specific diseases—bilary tract disease, hepatitis-B, and certain cancers—indigenous to those areas.

"Stanford researchers have a unique opportunity to collaborate with some sophisticated programs of investigative groups at these universities," Raffin said.

The program was spearheaded by Raffin, who first traveled to Japan and Hong Kong in 1978 to explore the possibilities of setting up such an arrangement. In 1981, the Ishiyama Foundation of San Francisco contributed $500,000 to the Department of Medicine to establish SAMFUND. The same year, Dr. Anthony Felsovanyi, clinical professor of medicine, traveled to Hong Kong with Raffin to establish an advisory board of civic and corporate leaders, who contributed another $500,000 to SAMFUND.

The advisory board members include Stanley Ho, chairman; Li Ka Shing, vice-chairman; Ho Tim; Ho Yin; Woo Hon Fai; Fung King Hey; Cheng Yu Tung; and Liu Lit Chi.

The organization's board of directors was formed in 1982. In addition to Raffin and Felsovanyi, the board includes Drs. Kenneth L. Melmon, chairman of the department of medicine and of the board; Richard Popp, vice-chairman of the deparment of medicine; and Ferid Murad, chief of medicine at the Palo Alto Veteran's Administration Medical Center.

The advisory board in Hong Kong is responsible for helping to support the Hong Kong-Stanford program.Similar boards will be established in other Pacific Basin areas including Japan and possibly mainland China.

Raffin said he hopes SAMFUND will attract sufficient funding to support these academic exchanges. Said Melmon of the program, "this is an important academic program with great potential for strengthening medical investigation in Asia and at Stanford."

BATTLING HERPES IN THE NEWBORN

STANFORD—

Infants born to mothers who never have had herpes simplex run a greater risk of being harmed by the disease than the children of women who have had recurrent bouts of the infection, according to a researcher at the Stanford University Medical School.

"The woman who has herpes is in good shape if she knows she has it," said Anne S. Yeager, associate professor of pediatrics at Stanford. "The problem comes for the mother who doesn't know she has it." Yeager described the dangers of herpes simplex and cytomegalovirus to fetuses and infants Tuesday (November 16) in the second of a series of public "Progress in Medicine" lectures on the herpes viruses.

Women who carry the virus chronically have antibodies in their blood which they pass on to a developing fetus as a protective cloak of immunity, Yeager said. But if a woman never has contracted herpes, or has contracted it recently, her infant is born without antibodies to the virus and, for the first few weeks of life, is vulnerable to an infection that can severely dammage vital organs such as the brain, liver and adrenal glands.

The two herpes simplex viruses (labeled HSV-I and HSV-II) that afflict at least 15 million Americans with recurrent cold sores and genital infections are annoying but non-life-threatening infections for most adults. HSV-I is responsible for most oral infections while HSV-II is most often linked to recurring genital blisters, though both viruses have the ability to attack mucous membrane anywhere in the body.

Yeager emphasized that both viruses are equally dangerous to infants in the first weeks of life and the mother is not the only source of infection. Grandparents or friends with open cold sores caused by herpes can occasionally transmit the virus through a kiss to the infant.

"Adults and children who have herpes and are in contact with an infant whose mother has never had herpes, and therefore has not passed on immunity to her infant, can give the baby the infection," Yeager said.

-more-

A decade ago obstetricians routinely delivered infants by Caesarean section if mothers had experienced an active episode of genital herpes sores within the last trimester of pregnancy. Once the sack of amniotic fluid that surrounds the developing infant during pregnancy ruptures in the hours before delivery, the child takes fluid into his lungs, along with any viruses present in his mother's birth canal. Via Caesarean section, physicians can remove the baby directly from the uterus before the sack is ruptured.

More recent studies have shown that men and women with herpes usually only are able to transmit the virus for a few days when open sores are present, so women with herpes now have routine vaginal deliveries unless they have an outbreak of sores the day of the delivery. Recurrent blisters last an average of nine days, and contagious virus cells are shed only during the first four days.

Yeager quoted studies from her own and other laboratories that indicate the group of susceptible infants may be even narrower. She cited a study conducted at Emory University several years ago which showed that three of six infants delivered vaginally who contracted herpes at birth all had mothers whose tissue cultures showed that they were shedding active virus the day of delivery. The three women were experiencing their first outbreak of the disease.

This study is frequently quoted, Yeager said, as evidence that 50 percent of infants exposed to herpes at birth will contract the infection.

"Less quoted is the fact that, in the same study, of the 23 women who had experienced recurrent infections (as opposed to primary infections) and were virus positive on the day of delivery, only one baby became infected." Yeager has since studied 204 women who had herpes sometime during their pregnancy, and none of the babies have developed the severe symptoms of a herpes infection. Apparently these infants were "protected" by antibodies they received from their mothers, Yeager said.

Though the remote possibility of "silent shedding"—transmitting the virus when no sores are present—exists, even this process could be detected through a tissue culture or blood test on the day of delivery. "We think eventually that it's not going to be so helpful to culture throughout the pregnancy, but perhaps only on the day of delivery to detect the virus," Yeager said. Infants who have definitely been exposed to active virus can then be watched for signs of disease and quickly treated with a battery of newly developed antiviral drugs.

-more-

"If the virus is suspected in babies, and the infants are offered anti-viral therapy within three days of the first sign of illness, as a general rule, they do very well," Yeager said. Studies are currently underway at Stanford and other research centers to determine whether the antiviral drug acyclovir or adenine arabinoside is more effective in treating neonate infections.

"The thing to remember is that only half of these babies have skin lesions. If you wait for the skin lesions to make the diagnosis, you're going to miss half the cases."

If a baby suddenly becomes lethargic or develops an enlarged liver or spleen and shows a sudden drop in platelets for no apparent reason, but doesn't have a bacterial infection, it probably has herpes, Yeager said. Premature infants are especially vulnerable to the disease and timeliness of treatment is crucial for these children.

Cytomegalovirus (called CMV) is a less famous member of the herpes virus family, but "overall may be of more importance to the average parent than herpes simplex," Yeager said. The virus is a threat because 50 percent of American women have never been exposed to the virus, so can't transmit immunity to their infants.

CMV can be transmitted through blood transfusion or through other body fluids. Yeager and her Stanford colleagues developed a screening test for donated blood in 1977 that has eliminated transfusion-acquired infections in vulnerable premature infants. Still, studies indicate that 15 percent of all pregnant women shed CMV virus sometime during their pregnancy, and can infect the developing infant.

"In addition to the one in every hundred infants who are born with the infection, five in a hundred will acquire it within six weeks of age," Yeager said. This figure compares to the one in 10,000 who develop defects from a congenital rubella infection acquired in the first trimester of pregnancy.

While effects of the infection can range from slightly stunted growth to mental retardation, liver dammage, and even death in some infants, the most common effect of CMV is deafness.

"It is especially important that these babies be identified early because there's good data that indicates that their hearing actually gets worse between one and two years of age," said the scientist. If the babies can be diagnosed early, they can often be treated successfully. "One out of every 100 American babies is born with this problem," Yeager said. "It is a major health hazard."

VACCINE ON THE HORIZON FOR HERPES PREVENTION

STANFORD—

A vaccine that prevents herpes simplex infections without exposing the recipient to the virus may be a decade away, said Thomas C. Merigan, Becker professor of medicine and head of infectious diseases at Stanford University Medical School. In the meantime, a new generation of anti-viral drugs recently approved for herpes treatment can curtail both the severity and duration of blisters though they can't keep the outbreaks from recurring.

"It looks like recurrence is still a problem, even with the most potent agents available today," said Merigan in a public lecture held at Stanford Tuesday (November 23) describing current and future treatments for herpes viruses.

Many of the 40 million Americans who suffer from recurring herpes blisters on their mouths or genitals wonder why effective treatments and vaccines have taken so long to be developed. The answer, Merigan said, lies in the large and complex structure of the virus which, until the advent of recombinant DNA technology, has been inscrutable to researchers.

"These viruses are also particularly challenging because they persist and can cause recurrent infections in the presence of immunity," Merigan said. "Once we are infected, we are infected for life, though the symptoms appear only periodically and, in most people, eventually disappear completely." In comparison to polio, which has a much smaller and simpler structure, herpes viruses are made up of a number of proteins in a complex structure.

When the active herpes virus, a naked package of genetic material, invades a cell in a patient, it takes complete control of the host cell's functions, diverting nearly all the cell's energy to the replication of viruses. In this way, thousands of copies of the virus are produced that can spread to other cells.

The problem with most anti-viral drugs is their toxicity. In order to thwart the virus, an effective agent must somehow influence the growth of the virus in infected cells. But, in many respects, herpes-infected cells look a lot like normal cells. The challenge to researchers has been to develop drugs that can zero in on infected cells without harming healthy ones. (Adenine arabinoside called ara-A) and acyclovir are two effective drugs now available to the public which have the necessary specificity, Merigan said.

First used in 1972 to treat herpes simplex infections in the eye, adenine arabnoside has a very similar structure to a component of the herpes simplex DNA. But the drug has an important structural difference: once incorporated into the genetic code of the virus, it turns off the action of an enzyme that the virus needs to reproduce itself. Once the virus stops replicating, the infection is arrested and can't be spread to other cells.

Acyclovir, an even more powerful drug, according to Merigan, works on the same target as ara-A, but has an additional degree of specificity. The drug, first used in clinical trials in 1979, only becomes active once it is inside a virus-infested cell. This specificity gives healthy cells, such as those in the bone

-more-

marrow that can be especially vulnerable to DNA-altering drugs, an added measure of protection, the scientist said.

The two antivirals have been especially useful in treating herpes infections in "immunosuppressed patients," such as those with organ transplants or some types of cancer, whose normal immunities to infections have been drastically reduced by the drug therapies they need to stay alive. Infections in such patients caused by herpes simplex or cytomegalovirus (CMV), another variant of herpes, can spread to vital organs such as the heart and kidneys and be fatal. Although the antivirals can't prevent infections, they can greatly reduce the serious complications associated with the infections, Merigan said.

Though a tremendous boon to immunosuppressed patients with prolonged herpes simplex infections, antivirals have been less useful for herpes sufferers with short-lived infections because the time in which they are most effective is the first few days of infection.

"These are exciting drugs, but they have to be given early," Merigan said, "probably within the first few days (after symptoms begin to develop)." Patients are often slow to bring the infection to the attention of their physician, and most hospitals are not equipped with viral diagnostic laboratories that can make a quick, positive diagnosis of herpes, he said.

Chronic, low-level doses of the drugs might be a solution for some patients, except that the virus could subtly change its structure and become resistant to such therapies. In addition, Merigan said, the possible side effects of long-term exposure to the drugs could outweigh the benefits.

Ultimately, the best way to stop a "herpes epidemic" is to prevent infection, and several research teams around the world are working on different types of vaccines that could do just that, Merigan said. An "attenuated virus" vaccine, injections of a live virus that has been altered slightly to give recipients a very mild virus infection without the accompanying disease, is useful against diseases such as polio or measles which can only be contracted once in a lifetime. Once exposed to the vaccine, the body makes antibodies and other factors to thwart a future infection.

But, because herpes can lie dormant in a patient without producing symptoms, recipients of an attenuated virus vaccine might run the risk of developing herpes years after the inoculation. Such an infection might be dangerous for patients who were healthy when they were vaccinated, but later became immune suppressed.

Recombinant DNA technology will permit a different kind of vaccine, Merigan said. As scientists break up the DNA of the virus into specific components, they are also able to isolate fragments that code for proteins on the virus surface. Such fragments have been used to make a vaccine in bacteria that can stimulate herpes directed antibodies in animals.

Thus, it might eventually be possible to initiate the recipient's natural immune response without exposing him to infectious components of the virus. In addition, further studies of immunity and resistance to infection will be required, Merigan said, to know how best to deliver this vaccine to produce enduring protection.

"I'm enthusiastic about the vaccines, but I think it's going to take at least another decade of research to perfect them," Merigan said. "But at least with recombinant DNA techniques, we have hope that they are possible."

SAFER, CRIBSIDE DIAGNOSIS FOR SICK INFANTS

STANFORD—

Stanford University scientists have demonstrated a new use for ultrasound diagnostics—to detect blood clots in the vessels of critically ill infants who are being monitored by umbilical artery catheters.

The use of noninvasive ultrasound, they hope, will spare newborn babies from the potentially negative effects of radiation, while providing doctors with a quick and safe screening method for a variety of catheter-associated complications.

These babies in the past have been subjected to the use of angiography, a method which provides doctors with X-ray visualization of blood vessels following the introduction of contrast material.

But now with his faculty colleagues, a Stanford resident, Dr. David Oppenheimer, has found that sonography—previously used effectively to *locate* umbilical artery catheters—is equally suited for detecting thrombosis, or clot formation, in the aorta and nearby arteries.

In a paper scheduled for presentation to the 68th Scientific Assembly of the Radiological Society of North America on Monday, Nov. 29 in Chigago, Oppenheimer explained, "Sonograms can be performed at cribside without removing infants from the intensive care environment. Diagnostic information is obtained without associated ionizing radiation and iodinated contrast material."

In a clinical study at Stanford, 71 neonates with umbilical artery catheters received a series of ultrasound exams. All echoes *not* representing the catheters themselves were considered indicative of an abnormality. (Normal arterial vessels, Oppenheimer said, are free of these types of echoes.)

In one instance the catheter itself, by completely filling an inner blood vessel, appeared to obstruct normal blood flow. This caused ischemia, or blood deficiency in the area, and normally present pulsation was absent. Vascular pulsations returned when the catheter was withdrawn.

(Oppenheimer explained that umbilical artery catheters are never used unless absolutely necessary in patient treatment, but that without them "many more babies would die." The umbilical artery provides the easiest route for monitoring patient hemodynamics, the movements and forces involved in blood circulation.)

Twelve infants had clinical signs of complications, including bluish or blanched extremities or toes, malfunction of a catheter, decreased peripheral pulses, leg swelling, and hypertension. Catheters had been in place between two and 35 days before symptoms developed. Ultrasound demonstrated abnormal echo collections of various sorts in ten of these infants.

-more-

Other causes were hypothesized in two symptomatic children with normal ultrasound exams. In one of these, the catheter had recently been removed, possibly causing an associated clot to fragment and then lodge in a more peripheral blood vessel. Oppenheimer said that most neonatal clots tend to resolve without the need for surgical intervention.

In his study he found that ultrasonically detected abnormalities persisted from two to more than 70 days. Many of these lasted long after the clinical symptoms had resolved.

In one baby, Oppenheimer said, the abnormality was mobile rather than fixed to the vascular wall. This moving "flap," he said, may have been causing the patient's hypertension. He hypothesized that the flap represented either a "floating" clot or a layer of vessel wall which had torn off during catheter insertion.

He added, "This type of abnormality has not previously been demonstrated in a catheterized infant. Our ultrasound exams led us to detect it."

Moreover, in a variety of cases ultrasound was able to identify clots and other obstructions causing ischemic symptoms in the babies. Further work, Oppenheimer said, is required to determine the long-term prognostic significance of ultrasonically detected vascular abnormalities and the impact of their detection on patient care.

What he has demonstrated, however, is that ultrasound is useful as a diagnostic tool in catheterized infants. "It is likely that future diagnostic techniques will provide even more accurate analysis of flow limiting lesions," he concluded.

Oppenheimer's research was supported in part by a grant from the General Clinical Research Centers Program of the Division of Research Resources, National Institutes of Health.

His report was co-authored by Drs. Barbara Carroll and Karen Garth of the Division of Diagnostic Radiology, and will appear in the December, 1982 issue of *Radiology*.

STOP SNORING WITH PALATOPHARYNGOPLASTY

STANFORD—

Snoring affects nearly half of all adults and can often threaten the snorer's health. But doctors at a recent conference of ear, nose and throat specialists in New Orleans, La. were told that snoring can be cured.

Severe cases of snoring can now be cured by a simple operation, long used in Japan and called palatopharyngoplasty, said Dr. F. Blair Simmons, professor of surgery at the Stanford University School of Medicine.

The procedure, said Simmons, was recently "discovered" in this country and it always works. In many cases, it stops snoring completely. In others, it significantly reduces the sounds of snores, "to levels that allow these patients' bed partners to sleep in the same room."

The jawbreaker word for snore-stopping surgery eliminates the problem by removing the offender's noise-maker—unneeded tissue in the upper throat.

As the sleeper breathes, the tissue vibrates and produces the nocturnal snorts and snuffles in much the same way blowing against the reed in a horn produces more melodious sounds. Snoring is an involuntary process and snorers cannot be conditioned to stop. The so-called "heroic" snorers are typically le and have their onset of snoring in their midthirties.

According to Simmons who has operated successfully on more than 80 patients, when one has an excessive amount of upper throat tissue, "excessive snoring always accompanies the condition."

"Anyone who snores in every position, is loud enough to be heard at least one or two rooms away and whose bed partner has moved elsewhere to sleep is a candidate for the treatment," Simmons added.

The operation was originally applied by specialists at Henry Ford Hospital in Detroit to treat sleep apnea. This is a life-threatening condition marked by cessation of breathing during sleep.

Earthquake-scale snorers actually may stop breathing for 15 seconds or more, several hundred times a night, then wake up with a loud snort as their blood's oxygen level drops. Sleep apnea causes daytime sleepiness and seriously taxes the heart and lungs.

At Stanford, Simmons said, half of the patients suffering from sleep apnea have benefitted from the operation. But the results also showed clearly that the social snoring problem of most other patients could be corrected with the new procedure.

"Snoring is socially a very big problem," Simmons noted. "It has been neglected by medicine because nobody knew how to treat it and it was considered funny to even try it."

Palatopharyngoplasty is as simple as removal of the tonsils. It is performed in a hospital under general anesthesia. It involves removal of about the back half of the soft palate, tonsils if they are present, and any extra tissue on the sides and back wall of the throat. After the unneeded tissue is removed, what remains is stretched and sutured together again. Postsurgical discomfort may involve a sore throat which requires a four- to five-day hospitalization.

"It's actually nothing more than a kind of facelift of the oral pharynx," Simmons explained.

STANFORD ASKS PATENT OFFICE TO CLOSE FILE ON RECOMBINANT D.N.A. FROM PUBLIC SCRUITNY

STANFORD—

Stanford University Monday, Dec. 6, asked the U.S. Patent Office to close the files on the patent application for recombinant DNA from public scrutiny until action on the application is complete.

Noting that the initial decision to hold the files open to public view was "unprecedented," Robert M. Rosenzweig, Stanford vice-president for public affairs, said Monday's action was "taken with some regret."

The initial decision to keep the file open to the public was "an experiment with some risks attached," he noted. "We were prepared to take the risk because of the wide interest in the subject of the application and because we believed we would emerge at the end with a stronger patent.

"The latter may still be true, but in our judgment, the experiment has failed. It is better to recognize that fact before more damage is done.

"Unfortunately, there has been no effective way to correct the erroneous public impressions resulting from the way in which the Patent Office acquires additional information. It does that by formally rejecting the application. The reason given for the rejection then tells the applicant what new information needs to be supplied.

"In practice, however, when an application is contested, the result of this process is to separate the allegations from the answers to them. As is so often the case when this happens, the charge is newsworthy but the answer to it is not. The two should appear together.

"When the application process is completed, the file will be open for public inspection. Until then, it is better that it not emerge in piecemeal fashion."

ARMAND HAMMER SALUTES LEVY'S RESEARCH ON MONOCLONAL ANTIBODIES

STANFORD—

A Stanford cancer researcher became the first beneficiary today of an annual prize established by the Armand Hammer Foundation to reward "the person or persons deemed to have made the greatest contribution to the cure for cancer."

Ronald Levy, a Stanford associate professor of medicine (oncology) will share the first $100,000 prize with an Australian researcher, George Telford Stevenson, for their research using polyclonal and monoclonal antibodies in the treatment of cancers of the blood and lymph glands.

First developed in England in 1975, monoclonal antibodies are proteins made by "hybridomas," biological factories created when scientists fuse an antibody-producing cell of the human immune system with a cell from a mouse tumor. Inheriting characteristics from both parent cells, the new hybridomas are able to produce virtually unlimited quantities of a desired antibody.

Once released in the blood stream, such antibodies travel throughout the body, seeking cells that carry matching protein "antigens" on their membrane coats. The antibody locks on to the antigen, labeling the cell for destruction by other cells of the immune system.

Levy and Stevenson adapted monoclonals for use as weapons in fighting leukemia and lymphoma of B-cells—blood cells in the human immune system that normally produce infection-fighting antibodies.

Stevenson found that leukemia cells of the B-cell type have proteins on their surface, called "idiotypes" which are not found on normal cells. In effect, these idiotypes serve as a finger print for the leukemic cell—a B-cell turned cancerous will produce millions of descendants all with the same fingerprint, and therefore all distinguishable from the normal B-cells and every other cell in the body.

Levy and his colleagues produced monoclonal antibodies against such idiotypes and are using the compounds in treatment. One patient with B-cell lymphoma was given multiple doses of such antibodies in 1981 when conventional therapy failed to halt his cancer. Eighteen months later, the patient is still in complete remission.

Though monoclonal antibodies seem promising in treating B-cell lymphoma, Levy cautioned earlier this year when the case was reported in the *New England Journal of Medicine* against making generalizations about the experimental therapy.

"The improvement of this patient's lymphoma with monoclonal antibody administration is a single observation that must be confirmed in other patients before we can draw any conclusions about the effectiveness of this technique," he said, adding that the characteristics of B-cell malignancies make them especially responsive to treatment with the custom-made antibodies in ways that other types of cancer might not be.

Levy, 41, graduated from Harvard University and received his M.D. degree from Stanford University in 1968. From 1973 to 1975 he served as a fellow of the Helen Hay Whitney Foundation in the department of chemical immunology at the Weizmann Institute of Science in Rehovot, Israel.

A member of the Stanford faculty since 1975, Levy has served on the editorial boards of the medical journals *Hybridoma* and *Blood*.

The following release was transmitted to wire services and Bay Area news sources Monday.

EDITORS:

(Because of the increasing frequency of heart-lung transplants, the Stanford Medical Center News Bureau will no longer routinely issue releases each time a heart-lung transplant occurs. Naturally, we will provide stories when conditions make a particular transplant newsworthy for scientific or human interest reasons. Reporters, of course, are welcome to call with queries about individual patients in the program, and we will respond just as we have for heart-only transplant patients. The News Bureau welcomes your suggestions about how we might better provide each of you with information most relevant to your needs and the interests of your audiences.)

STANFORD PERFORMS 10TH HEART-LUNG TRANSPLANT

STANFORD—

A San Rafael, Calif. man Monday, Dec. 6, became Stanford's 10th heart-lung transplant patient, the third recipient of such surgery here in just over a month.

The patient, Frank LaForge, was born with a heart defect which had relentlessly caused his health to deteriorate throughout his 27 years, said Dr. Stuart Jamieson, assistant professor of cardiovascular surgery and head of the heart-lung program. Jamieson led the five-physician team which performed Monday's five-hour surgery.

On Monday, LaForge was reported in critical but stable condition, the standard designation immediately after the double transplant. On Tuesday, he was taken off the respirator at 6:30 a.m., and still listed in critical but stable condition.

Two other heart-lung transplants, Philip McGrath, 22, East Islip, N.Y., and Ronald Grunden, 40, Ventura, Calif., were reported in stable condition Tuesday. McGrath, who received his replacement organs Nov. 9, and Grunden, whose operation occurred four days earlier, were both progressing and are able to walk around as they gain strength, the doctor said.

-more-

All three of the most recent recipients suffered from ventricular septal defects (VSD), characterized by holes between the left and right chambers of the heart. This allows blood to flow between the chambers, resulting in too much blood entering the blood vessels in the lungs. Eventually, the overcirculation causes pressure to increase in the pulmonary arteries, and the right ventricle of the heart is unable to overcome the pressure.

In recent years, surgeons often have been able to correct the condition in infants. If left uncorrected, however, both the heart and the lungs become irreversibly damaged.

LaForge is married and had worked as an accountant until his condition deteriorated and he was forced to restrict his activities severely. Jamieson said his life expectancy was estimated at only a few months without the operation.

"Our research and clinical experience indicate that the heart-lung procedure is a viable therapeutic treatment for these patients," Jamieson added.

"We are limited in our efforts to perform these procedures by the number of families who are unaware of the urgent need for donors. We and the families of our recipients are indeed grateful to families who make this program possible."

Despite the encouraging prognosis for the latest patients, Jamieson cautioned that all three men face lifelong regimen of monitoring and medication intended to prevent the body's tendency to reject the new organs.

LaForge is the 10th heart-lung transplant patient since Stanford began its program March 9, 1981. Seven of the patients, including the first recipient, are doing well. Three of the patients died, all within a month of their operations.

Heart-lung transplants were first performed 12 years ago, but all three patients—transplanted in South Africa, Texas and New York—soon died.

The procedure was revived here last year with the discovery of Cyclosporine (formerly called Cyclosporin A), which allows the windpipe to heal while working to prevent rejection.

Cyclosporine has also been used at Stanford since December 1980 on heart-only transplants, and Jamieson and his colleagues credit its use in helping to increase the one-year survival rate to approximately 80 percent. Stanford has performed 248 heart transplants since Dr. Norman Shumway pioneered the procedure in this country in January, 1968.

CLINICS RENOVATION TO BEGIN AT STANFORD

STANFORD—

A construction firm in Foster City has signed a contract with Stanford to undertake a major program to extensively upgrade the physical facilities of the Stanford University Clinics.

The project involves renovation of the first two floors of the Boswell Building, the facility adjacent to Stanford University Hospital where a majority of the 82 outpatient medical clinics will be located.

The $6.5 million construction, equipment and remodeling program was approved last June by the University's Board of Trustees. Improvements will include completely redesigned and larger patient treatment rooms, achieved in part by construction which expands clinic space into a few feet of what is now the building's courtyard.

Other improvements will be: decongested corridor traffic; a larger outpatient pharmacy; expanded office and storage space; four treatment rooms and five recovery spaces in a special procedures suite, to accommodate minor surgical procedures not requiring overnight hospitalization; and a better overall atmosphere. The renovation plan includes increasing the size and number of clinics to be accommodated in the Boswell Building by moving certain academic and research functions elsewhere.

The firm S.J. Amoroso signed as general contractor for the project Tuesday, Dec. 7, following signatures a week earlier by Dr. Lawrence G. Crowley, vice president for medical affairs at Stanford, and William Massy, vice president for business and finance. The total construction contract is for $3,852,600, according to Betty Rose, assistant director of Facilities Projects at SUMC.

"The modernization of the Boswell Building is a first step in our efforts to expand the dimensions of faculty medical practice in order to serve the community more effectively, and with the maximum comfort for our patients," said Donald Tower, director of the Stanford University Clinics and Faculty Practice Program.

"The Faculty Practice Program is being reorganized," he added, "to provide comprehensive medical care, consultation, diagnosis and treatment, sharing responsibility for the sustained good health of families choosing faculty physicians as their doctors.

"These physicians will work as a team to bring their specialized areas of knowledge and experience to the patient's medical problem."

-more-

Presently, the specialty and subspecialty clinics, staffed by faculty physicians, receive about 135,000 visits per year, with patients referred from all over northern California, the west, other states and even other countries, Tower noted.

Work will begin under the 880-day contract Dec. 22, although the beginning stages of construction are not expected to impact the normal activities of patients and staff. In fact, said Langston Trigg, Jr., assistant director of Facilities and project manager, there will be little disruption of patient care throughout construction, because of the staged approach to the project.

Periodic updates on the status of construction will soon be available to patients and others at an information booth located near the front entrance of the Boswell Building.

The Boswell Building was built in 1959, and has had only minor, occasional renovation since. The present renovation is intended to make the Clinics a more comfortable and efficient place for patients to seek medical care.

The Boswell Renovation and related projects will result in relocation of many of the clinics. The clinics to move are: Cardiovascular Surgery; Dermatology; Medicine (allergy, cardiology, chest, endocrine, gastroenterology, hematology, immunology, internal medicine, nephrology, preventive medicine, and Stanford Medical Group); Neurology; Pain Clinic (already moved); and Surgery (eye, general surgery, hand, orthopedics, plastic and reconstructive, thoracic, and urology).

The clinics to remain where they are include: Gynecology/Obstetrics; Medicine (oncology); Pediatrics; Psychiatry (including Sleep Disorders); and Surgery (audiology, ENT, neurosurgery, and pediatric surgery).

The Clinics are a separate outpatient care facility from Stanford University Hospital since September, 1981. They have a close relationship, however, with both the Hospital and the Stanford University School of Medicine, the three interdependent components together comprising the Stanford University Medical Center.

"For the past two and a half years we have been analyzing the Clinics' needs," said Trigg, who will be assisted by Erik Lund of Facilities. (Lund will handle the project once construction begins.)

"For example," said Trigg, "among changes will be a shorter journey for orthopedic patients from their clinic to X-ray. The ophthalmology clinic, which obviously serves the largest percentage of visually impaired patients, is specifically being placed in an easy-to-find location," he added.

"A lot of changes which superficially might be seen as technical or procedural will in fact make visits to the Clinics more comfortable for patients."

-more-

For example, Vera Waechter, R.N., assistant FPP director for the Clinics, said that patient registration is being decentralized to the individual clinic areas.

"This will reduce the amount of time patients will have to wait before seeing their doctor, since they will no longer have to check in with a central desk and then with a receptionist at their individual clinic," Waechter said.

She added, "We're proud of the quality patient care provided at our clinics by Stanford medical faculty, and we'd like the physical setting to reflect that high quality." In that respect Waechter hopes to see positive results for the Clinics over the next few years.

Designers of the Boswell Clinics Renovation Project are Almeter and Finley, Architects of Palo Alto.

Funding will come from private sources, including a major gift from the James G. Boswell Foundation, the original contributors to the existing facility. Additional gifts to Stanford University Medical School for the Boswell Clinics Renovation Project are still being sought and gratefully accepted. Part of the costs will be covered by the Faculty Practice Program and the Medical School's capital budget.

Inspector for the project will be Morrie Grove of the SUMC Facilities Projects Office, under the direction of Howard Mark, manager of construction.

The improvements are intended to prepare the Clinics for technological advances in medicine in the coming years. They are also designed for greater flexibility than is now provided. Additional conference rooms will be added for teaching purposes in the Clinics area, said Trigg.

During construction, things may sometimes seem hectic in the Boswell Building, he added. There will be some noise, and perhaps some dust near construction areas. The final benefits, however, are hoped to outweigh the temporary inconveniences which may occur.

"Since greater convenience for all is the ultimate goal, everyone's cooperation and patience should prove more than worthwhile," added Tower.

TAMING THE SIDE EFFECTS OF WHOOPING COUGH VACCINE

STANFORD—

A Stanford neurologist has found genetic clues which he believes could help predict which children are most likely to be harmed by whooping cough vaccine.

The answers may help doctors decide who should be vaccinated and who shouldn't.

"The whooping cough vaccine is one of the crudest vaccines currently given to kids," said Lawrence Steinman, assistant professor of neurology. "It's the whole organism, killed and ground up for injection."

When a few healthy British infants developed brain damage and epilepsy a few days after routine whooping cough immunization several years ago, some parents panicked and refused to have their children vaccinated.

The result: more than 100,000 children contracted whooping cough, and at least 30 died.

"But for now, the vaccine has to be used because the risk of reintroducing the natural disease in the community is higher than the rare complications from the vaccine," Steinman said.

Controversy over the vaccine continues, although most physicians agree that the dangers of the disease outweigh the risks of immunization. While whooping cough is not itself fatal, it can leave a child vulnerable to viral pneumonia and other infections that can kill him.

In a study published recently in the British science journal, *Nature*, Steinman reported injecting several inbred strains of mice with the vaccine. While a fraction escaped unscathed from the experiment, all the animals possessing specific factors in their genetic code suffered convulsions and died within two hours of immunization.

Autopsies of the mice showed physical and chemical changes in their brains that were "nearly identical" Steinman said, to the damage found in the brains of children who died after receiving the vaccine.

The genetic factors that the stricken mice had in common were located on the "immune response chromomsome," the cluster of genes in every cell that seem to control how an animal responds to infection.

Humans have an analagous gene cluster called the "histocompatibility complex." In the last decade, scientists studying the complex have recognized that some genes appear more frequently in persons with certain diseases.

-more-

Multiple sclerosis, juvenile diabetes, and "poker spine" all are associated with specific genes which physicians sometimes can use as easily detected signposts for disease susceptibility. But Steinman's work is the first hint that adverse responses to routine immunizations might also be under genetic control.

Research teams in England have just begun studies of children who develop complications from the vaccine, in hopes of finding a similar genetic marker. "We hope to identify a subpopulation of children who are at greater risk and exclude them from immunization," he said.

Currently one in 1,000 children who receive the vaccine will develop mild fever or irritability, and one in 50,000 will suffer severe brain damage.

"One out of 50,000 is not very many except that when every kid gets the vaccine, it takes its toll," Steinman said. "But five times that number will be damaged if we don't immunize. It's a risk that I think is worth taking, but it's a situation that should be improved."

The vaccine research was funded by a grant from the National Institutes of Health.

TRUSTEES OKAY FURTHER PLANNING FOR ANIMAL FACILITY

STANFORD—

Stanford University School of Medicine Monday (Dec. 13) received approval by the University Board of Trustees to proceed with final planning for a new, modern animal research facility.

The project, estimated to cost between $10 to $12 million, envisions a single-level underground facility located south of the Sherman Fairchild Auditorium. The facility of approximately 32,000 gross square feet, will be connected to the main Center by an underground tunnel, and will replace approximately half of the existing animal research facilities of the School of Medicine, which do not meet present codes.

The facility would be equipped with ventilation stacks about forty feet above ground and located in the greenbelt near Campus Drive. Parking space adjacent to the Fairchild Auditorium would be restored after construction of the facility is completed.

The trustees approved the building site based on drawings prepared by the architectural firm of Stone, Marraccini and Patterson of San Francisco, the project's consultants. Completion of design is expected by early summer of 1983, with construction scheduled to begin shortly thereafter. The building is expected to be completed in late 1984.

The project will be funded by about $3 million of University and Medical School reserves, and the balance will be a candidate for financing by tax-exempt bonds through the California Educational Facilities Authority (CEFA), according to David Mendelow, associate dean for administration.

"Laboratory animals are an essential component of biomedical research," said Dean Dominick P. Purpura of the School of Medicine. "Virtually every new surgical procedure is first tested for feasibility and safety in animals. No new medication is ever released for application in patients without extensive animal testing for efficacy and toxicity.

"In the basic sciences, advances in such fields as immunology, physiology, and microbiology are owed to studies in animals.

"A prerequisite to the use of animals in research is that they be maintained in excellent health and as free from stress as possible. While there is active research to find alternatives to animal experimentation when possible, it is fair to say that for the foreseeable future, laboratory animals would continue to play an important part in basic and clinical research."

Three quarters of the Medical School's principal investigators make use of laboratory animals in their studies. On the average, close to 30 different species or types of animals totalling 8,000 are accommodated within the facilities of the Medical School's Division of Laboratory Animal Medicine. An additional 45,000 animals, principally rodents, are held in departmentally administered facilities within the Medical School, according to Mendelow.

"Existing facilities do not properly support the extensive animal-related research programs of the School," Mendelow said. "They are not in compliance with applicable codes and guidelines, and are difficult to maintain and poorly designed for effective use.

"External agency reviews in the past two years have substantiated the urgency of instituting corrective measures," he added. "While temporary measures at a cost of $1.3 million have been taken to alleviate deficiencies, these are not sufficient."

The proposed facility, Mendelow said, would permit improved quality animal care, and centralized operations, with greater efficiency.

STANFORD—

Planning for the new construction and remodeling of Stanford University Hospital continues, though with some reductions in the amount of initial work to be done.

The Hospital Modernization Project staff reported at the regular Dec. 15 meeting of the Board of Hospital Directors that these revisions would not reduce the scope of the master plan for the hospital.

Planners and architects had been working during the past several months on belt-tightening measures for the project. The revised plans are designed to take into account uncertain future reimbursement levels and a changing economic climate, according to Elvia Garwood, director of the project.

"Our needs for a project of the same scope as originally planned have not changed," she said. "But we wanted to prepare for a less favorable financial climate, and build into the plans somewhat reduced initial construction and modified remodeling phases. This will extend the time for completion of some parts of the project, but preserve the modernization program objectives. The design takes into account construction options which may be included when the financial picture improves."

The new plans call for construction of a new addition near the north end of the present hospital which would be devoted entirely to direct patient care. Earlier plans had called for three structural elements with part of each devoted to administrative and support activities.

A planned new wing for diagnostic and treatment services is also reduced in the initial construction phases. Eighteen new operating rooms would be constructed, instead of the original 22. Four existing operating rooms, two at the main center and two at Hoover, would be maintained.

The modernization is designed to take place in three steps, beginning with completion of the Phase I building expansion of 1978, then adding in new construction a diagnostic and treatment wing and the first segment of eight new nursing units of 22 to 24 beds each, and lastly remodeling existing areas to meet building codes. Construction could begin as early as April 1984.

These first steps allow for the closing of 83 beds at the Hoover Pavilion. The long range plan calls for complete closing of Hoover and the beds are accommodated in subsequent new construction at the main center.

Current plans also take into account the consolidation of Children's Hospital at Stanford that ultimately will be located adjacent to the new nursing units at SUH.

As outlined to the Board of Hospital Directors, the initial stage of the project would have a construction budget of $62 million and a total project budget of $100 million. Earlier budgets were $78.4 million for construction and $123.9 million total project cost.

Sheldon S. King, executive vice president and director of SUH, said the new directions represent "a very solid plan, which meets our critical needs for bringing the physical structure of the hospital into balance with the advanced state of care provided to our patients."

The project focuses more on modernization than expansion of services with only six new beds (for neonatal intensive care) added to the total current bed capacity of 663.

The hospital modernization is being designed by the Naramore Bain Brady Johanson Group, an architectural firm based in Seattle with an office in Palo Alto.

BATHS, BIOFEEDBACKS CAN BE ASPIRIN SUBSTITUTE, PSYCHATRIST SAYS

STANFORD—

The best aspirin substitute for a tension headache might be relaxation training, biofeedback, or perhaps even a nice hot bath, says a Stanford psychiatrist.

Besides avoiding the small but ever present medical risks of any medication, people who turn to nonpharmaceutical solutions for simple tension headaches receive "an extra dividend, a philosophical advantage.

"People feel so much better when they're not dependent on drugs," explained Dr. Stewart Agras, professor of psychiatry and director of Stanford's Behavioral Medicine Clinic.

"There is a growing feeling that people should take control of their own health care. What better way than to shift from drugs—a passive solution—to self-management."

The holiday season is a time of high stress for many people, a time when the muscles in the neck and head are prone to stiffen, producing a classic tension headache.

"For many people the answer is as simple as a warm, relaxing bath. Or perhaps they just need to stop for a moment and take the time to calm down."

For more persistent headache problems, Agras said, relaxation training or biofeedback might help.

"Although we do not have scientific research comparing the effectiveness of these techniques with such drugs as aspirin, aspirin substitutes or mild tranquilizers, we have found in the clinical setting that many patients have had excellent results. Some patients have become headache-free using these techniques after using medication for years without success.

"We also have 15 or 16 thorough studies conducted around the country which show that biofeedback and relaxation training are more effective than placebos" ("fake" pills which subjects believe are real medicine).

Typically, relaxation training involves seven or eight weekly sessions where patients are coached on how to consciously make various muscles of their body become tense and then relax. Patients practice at home for 20 minutes every day using tape recordings which reinforce the message learned in class.

-more-

Biofeedback involves many of the same techniques but uses electronic equipment to show a visual picture or audio interpretation of blood pressure or heart beat. This enables the patient to strive consciously to alter positively these symptoms of tension.

"Most people would want to try relaxation training first before being hooked up to $20,000 worth of equipment," Agras said.

Agras cautioned that "since headaches can sometimes be symptoms of more serious problems, people might be well advised to check with a physician to rule out the possibility that their headaches are being caused by something more serious than tension."

Everyone clearly is not a candidate for relaxation training or biofeedback, Agras said, "but if you're getting a tension headache just about every day for about 20 minutes, it might be something to consider."

Agras said relaxation training and biofeedback are becoming widely available through clinics, community colleges or on referral from physicians. Stanford provides such services under the auspices of its Behaviorial Medicine Clinic.

The psychiatrist said he won't rule out the use of an occasional aspirin, aspirin substitute or mild tranquilizers. He said aspirin itself seems to be the most effective of the three groups, and that its potential side effects—such as stomach upset or ringing of the ears—are usually not serious.

And for non-tension headaches, the ones that occur in minor epidemic form during the holidays from overeating or too much drinking, Agras recommends the most simple solution of all:

"Moderation, or if that fails, a large glass of water or perhaps juice. These headaches are caused by a loss of body fluid."

Three quarters of the Medical School's principal investigators make use of laboratory animals in their studies. On the average, close to 30 different species or types of animals totalling 8,000 are accommodated within the facilities of the Medical School's Division of Laboratory Animal Medicine. An additional 45,000 animals, principally rodents, are held in departmentally administered facilities within the Medical School, according to Mendelow.

"Existing facilities do not properly support the extensive animal-related research programs of the School," Mendelow said. "They are not in compliance with applicable codes and guidelines, and are difficult to maintain and poorly designed for effective use.

"External agency reviews in the past two years have substantiated the urgency of instituting corrective measures," he added. "While temporary measures at a cost of $1.3 million have been taken to alleviate deficiencies, these are not sufficient."

The proposed facility, Mendelow said, would permit improved quality animal care, and centralized operations, with greater efficiency.

STANFORD DEVICE IMPROVES ULTRASOUND IMAGING OF INNER EYE

STANFORD—

A new device developed at Stanford University greatly improves ultrasound imaging of the inner eye.

Called the A/B Scan, this machine's basic components are a hand-held probe and a television screen, but its electronics are so complex they will enable opthalmologists to make more precise diagnoses than ever before.

Doctors can now view a "real-time" or television-like picture of events in the eye, thanks to the work of electrical engineering Prof. James Meindl, Alan Susal, a physician specialist in opthalmology, and Terry Walker, a senior engineering research associate at the Stanford Electronics Laboratory.

The group began work on the B scanner in the spring of 1977, after the National Institute of Health issued a supplemental grant to Meindl and the Electrical Engineering Department. The machine was licensed through Stanford's Office of Technology Licensing and is being manufactured and shipped by STORZ Instrument Company of St. Louis, Mo., which specializes in the sale of opthalmic equipment.

The scanner may be used for imaging small body parts, Walker said, but it was designed primarily for opthalmic exams.

The machine is used every Tuesday at the Stanford Eye Clinic under Susal's direction. "It has the clinical features that one would expect from a whole new generation of technology," Susal said.

The patients examined by the scanner have special problems, according to Walker.

"Usually the nature of the problem is that there is something wrong with the eye that makes it difficult or impossible to see into it visually," he said.

For example, the patient might have a cataract or a hemorrhage from an accident. The opthalmologist then needs to determine the feasibility of surgery, and "the only way to find out is to use ultrasonic imaging," Walker said.

Machines called static B-scanners have been used in the past but they are not able to provide any information about movement within the eye, which is important in telling if a retinal detachment can be repaired.

A B-scan instrument is one which produces a cross-sectional image of the part of the body that is being studied.

The probe has 32 transducer elements on the front of it, and in the case of the eye, the transducer face is placed against a special liquid on either the cornea or the eyelid, depending on the case. Ultrasonic beams are sent out from the transducer elements in a sequence, forming the scanning process.

"It works like a radar system, so if there's anything out there that produces a disturbance in the medium, either a tissue or changes in the type of medium, like going from water to the vitreous humor that's inside the eye, you get an echo," Walker said.

The transducer is a special type of electronic material which translates an electrical force applied to it into sound waves. When ultrasonic echos come back from the eye, they are converted back into electrical signals and then amplified in the probe and sent to the computer behind the television screen.

-more-

Each transmission and echo sequence takes 80 millionths of a second. The entire sequence occurs 60 times per second, and the television display that is on the main instrument is synchronized with this time period.

"So you get 60 complete ultrasonic images a second on the screen so that it produces a real-time moving image on the display, and that's an important feature," Walker said.

Machines in the past were only capable of displaying an image eight of 10 times per second, according to Walker, and therefore, the image would jump or flicker on the screen. "On this one the scanning is fast enough at 60 times a second so that you get a perfectly smooth motion, just like watching ordinary TV or a movie," he said.

A problem in producing a real-time image is that it is necessary for the returning echo to be matched up with the transducer element it was sent from. The matching process, called electronic multiplexing, is done with special integrated circuits developed in the Integrated Circuits Laboratory at Stanford.

The circuits, which Walker referred to as "a key ingredient to the production of this type of instrument," were first developed by electrical engineering Prof. James Plummer under an NIH grant on ultrasonic imaging. Walker and Plummer modified them for the A/B Scan and they are now being produced for STORZ by a commercial firm.

When the echos from the transducer get to the main instrument, they are amplified and processed by a "fairly sophisticated radio receiver."

"That's all handled by complex digital electronics custom-made specifically for this," Walker said.

By designing a memory unit that is divided into many sections, the scan's designers were able to produce another innovation: the data is stored into a memory unit at the same time it is being presented on the television screen.

The information is not only stored in the computer, but it can also be put onto a videotape, which can be used in any standard video player. "The doctor can then play it back at his convenience later and reexamine the patient and see if he missed anything," Walker said.

Markings, such as patient number and lines indicating measurement, normally on the machine's screen are also put onto the tape.

The screen has two main displays: the upper region corresponds to the B-scan. The lower to something called an A-scan.

The A-scan is generated by a separate circuit, "which allows you to select some part of the center of the image and display as a function of distance, the strength and echo," according to Walker.

The computer that controls the whole system is "user-friendly" or user-oriented, Walker said. "That is to say all of the controls on the control panel were thought out very carefully as towards what the user wants to do, not necessarily what the machine wants to do."

Three buttons on the probe also provide a convenience for the physician. They are duplicates of buttons on the main instrument but allow the doctor to examine the patient and look at the display without having to reach over to it.

One of the buttons is for "frame freeze," which allows the doctor to study an image for a longer period of time. Walker said that an opthalmologist might stop the picture and then instruct the computer to set some marks on the screen and measure the distance between them, equivalent to the distance in the eye.

Precise measurements are important when a patient needs a cataract lens replacement, Walker said, "because the lens which is put in has to have the proper strength or the person won't be able to see without using strong glasses."

MEDICAL STUDENTS LEARN ABOUT COST-CONTAINMENT

STANFORD—

The education of most medical students includes anatomy, pathology, and the usual basics. Students at Stanford University School of Medicine learn the basics, and much more. In a novel addition to what perhaps is the core of medical education, clinical medicine, students are learning how to make clinical decisions incorporating a relatively new medical concept—cost containment.

"Health care costs have become a real concern in the past decade, so there is a big interest in cost containment," said Dr. Harold Sox, Jr., associate professor of medicine (Clinical).

"The course we teach has come into its own time. It wouldn't have been taught five or ten years ago," added Dr. Keith Marton, assistant professor of medicine.

The concept behind the course, Sox explained, is that costs are generated by physician decisions about the treatment of their patients. What test to administer, whether to admit patients to a hospital, and how long to keep them there, for example, all affect the total cost of health care. If physicians learn to make the best possible decisions, the costs will be kept to a minimum.

Physicians, estimates show, control as much as 91 percent of expenses for hospital services, and 76 percent of expenses for physician services.

Sox and Marton teach students to make decisions by using probabilityto express their uncertainty about the diagnosis, and something called Bayes Formula, an algebraic formula that "allows the clinician to answer the all-important question: 'how likely is it that my patient with this test result has disease X?' "

Consider, for example, a patient in the hospital recovering from a hip replacement, Sox said.Suddenly, he experiences shortness of breath, and his heart rate elevates. His physician immediately thinks he may have pulmonary embolus, a blood clot that starts in the legs and sometimes travels to the lungs. Any of three tests could possibly determine the cause of the patient's symptoms. To determine which test to give, Sox continued, the physician must know how likely it is that the patient does, in fact, have pulmonary embolus, based on the history and physical examination; the frequency of false positive and false negative results; and the minimum probability at which the physician would treat the patient for pulmonary embolus.

On the basis of this knowledge, the physician can determine which of the three tests will be of the most value, and administer it without wasting time and money administering the other two.

While this formal procedure may seem unnecessary for physicians with years of diagnostic experience, it is a boost for medical students or new physicians.

Sox and Marton also teach students decision analysis, using a "decision tree" to weigh the benefits and doubts of alternative treatments.

"The attitude used to be to try one alternative, and if that didn't work, try the next option on the list," Sox said. "We teach students to determine which test is best to administer, and to forecast the effects of various tests' results on what they would do for the patient, in order to decide which is the best treatment option."

Not only is the subject matter innovative, but the way in which it is taught is unique also. Sox, who started researching medical decision making about ten years ago, got together with Marton and Michael Higgins, Ph.D., a medical decision analyst. With a two-year grant totaling almost $59,000 from the Schering-Plough Foundation through the National Fund for Medical Education, they put together a series of lectures on medical decision making, and recorded them on videotape.

Over the past two years, they've tested various methods of teaching the material. The best, they've concluded on the basis of a controlled study, is tutored videotape instruction. A small group of students watches the videotapes, and a tutor is present to answer questions, emphasize specific points, or be of assistance in any other way necessary.

"We are really impressed by the students' interest in the material," Sox said.

The team has already sent the videotapes to two other medical schools, and is working on a handbook to go along with them. "There is no comparable opportunity at other medical schools to learn about medical decision making in this way," Sox said. "We've gotten a lot of requests for the materials. We'd like to make them more available to other schools."

STANFORD—

Myron L. Weisfeldt, professor of medicine at Johns Hopkins University, will discuss "Age Associated Alterations in Cardiac Function and Exercise Response" at 5 p.m., Monday, Jan. 17 in Fairchild Auditorium at Stanford Medical School.

Weisfeldt serves as director of the division of cardiology at John Hopkins in Baltimore. His major areas of research interests have been in aging changes in cardiac function, ventricular function, ischemic heart disease, and more recently in certain aspects of cardiopulmonary resuscitation.

The talk is the 16th John Kent Lewis Memorial Lecture, named in honor of a Stanford physician and scholar who died in 1961. The lectureship seeks to bring outstanding cardiologists to lecture at Stanford, said Donald C. Harrison, chief of the cardiology division at Stanford.

The talk is open to the public and continuing education credit is available for physicians.

THE END OF THE NURSING SHORTAGE

STANFORD—

Two years ago, Stanford University Hospital (SUH), like all hospitals, faced a severe nursing shortage. Today, in a completely reversed situation, it is finding itself with too many nurses.

"We are not doing any hiring," said Duane Walker, R.N., M.S., director of SUH nursing services. "Two years ago the turnover rate was 37 percent, which was very low nationally. Now it is less than one percent."

What's more, Walker added, nurses want to work more hours. "Sixty percent of the nurses here are the primary wage earners. They can't afford to work less than fulltime anymore," he said.

Three units at SUH have closed indefinitely because of low patient census. The nurses, and patients, have been transferred to other units. Unlike many other hospitals, Walker said, SUH has not laid off any nurses. Instead, they are being asked to take a day off—about one each month—to compensate for the decreased need for their services.

"The nurses are responding very well. They would rather take a day off than see their colleagues laid off," Walker said.

"Its much more difficult to have too many nurses than not enough nurses. The feelings are much more intense when they see less money in their paychecks. We are trying to be fair, however. We're working closely with the nurses' union to ensure job security," he continued.

With the oversupply of nurses, the massive recruiting efforts of two years ago have been cut back as well. SUH representatives used to go on about 20 recruiting trips each year, in addition to attending all nursing conventions, Walker said. Now, they have combined their efforts in about ten trips per year. "We still want to maintain our visability," he explained., "so we can continue to attract the best nurses."

In order to do this, they are keeping up their marketing efforts. "Rather than saying 'come to Stanford', we market the reserach, education, and work programs we have here. We still get a lot of inquiries from nurses all over the country," he said.

The current situation is the opposite of two years ago, when nurses had their pick of jobs. Hospitals actively recruited them, offering every possible incentive from flex-time scheduling to monetary bounties to get them to come to work.

Walker credits the distressed economy with causing the oversupply. People are unable to afford health care, foregoing elective procedures and keeping essential hospital stays to a minimum. The result is too many empty beds; many hospitals have been forced to close entire units due to low census. An annual American Hospital Association survey showed a 13 to 21 percent decrease from 1980 to 1981 in the number of nursing job vacancies. And high unemployment rates are forcing many nurses, who would otherwise choose not to work, back into the job market.

Nursing schools are responding to the oversupply by cutting back on their programs and the number of students they accept, Walker said. "If the economy comes around the situation will change, and there will be a shortage again," he predicted.

PHYSICIAN ASSISTANT APPLICATIONS SOUGHT

STANFORD—

Qualified minority candidates for the Primary Care Associate Program are currently being recruited by the Community Outreach Project at Stanford University Medical Center.

Application forms for the first-year class beginning September, 1983, are now available upon request, and along with all supporting documents must be returned by March 15, 1983.

The two-year program trains highly skilled health providers called physician assistants (PAs). Selected are mostly students showing a strong commitment to work in medically underserved communities. Through the program, they gain the academic and clinical experience they need.

PAs and family nurse practitioners function in association with physicians in the maintenance and delivery of primary health care in areas—primarily rural or inner-city—in which there is a shortage of physicians. PAs can handle many medical tasks.

The Primary Care Associate Program was established at Stanford in 1973, and is administered in cooperation with Foothill Community College in Los Altos. The program is run jointly with a consortium of community colleges around the state.

The first year of training is spent in pre-clinical classroom work at one of the consortium colleges. Clinical work carried out during the second year is coordinated through Stanford and consists of didactic and clinical teaching at the Medical Center as well as preceptorship training with a physician in the community.

The Community Outreach Project was initiated in 1980 by the Primary Care Associate Program specifically to recruit minority applicants.

To obtain application forms or for further information regarding a career as a PA, contact George Villaneuva at the Primary Care Associate Program, 703 Welch Road, Suite F-1, Palo Alto, CA 94304; or phone him at (415) 497-6431. Applicants must be U.S. residents or have a permanent visa.

HEALTH CARE FOR INDIGENTS TRANSFERS TO COUNTIES

STANFORD—

Stanford University Medical Center physicians were notified this week by Chief of Staff James Silverman that because of the state's restructuring of the Medi-Cal program January 1, the responsibility for care of Medically Indigent Adults (MIAs) is being transferred to county governments.

This means that there will be no reimbursement to the hospital for any care given to such patients, and they should be referred to county health facilities.

MIAs are generally low income adults, between 21 and 64 years of age who have major medical needs, are not otherwise eligible for Medi-Cal, and who cannot pay their hospital or doctor bills. They are often called the "working poor."

Both community and faculty physicians at Stanford were sent information about the new law in a letter from Dr. Silverman. He noted that patients who are not covered by private health insurance, Medicare, Medi-Cal or who cannot pay for hospital health care services, will be referred to county health facilities, based on their county of residence.

The physicians were asked to refer MIA outpatients to county clinic facilities. Inpatients will only be admitted to Stanford if emergency care is needed, and they will need to be transferred when their condition stabilizes. Emergency care will be provided regardless of the patient's ability to pay.

Santa Clara county residents will be directed to Santa Clara Valley Medical Center, 751 Bascom, San Jose, telephone (408) 279-5100.

San Mateo county residents, to Chope Community Hospital, 222 W. 39th Avenue, San Mateo, telephone (415) 573-2222.

Residents of San Francisco county will be referred to San Francisco General Hospital; Marin county residents to Marin General Hospital; Alameda county residents to Highland General Hospital, Oakland; and Contra Costa residents to Contra Costa County Hospital in Martinez.

Before the new law, MIAs could receive Medi-Cal benefits at any hospital in the area. The state reimbursed the hospital a percentage of its cost of providing the care. Under the new law, these patients can no longer receive public assistance benefits at whatever hospital they or their physician choose, but must use county-designated facilities.

MIAs comprise about three percent of the total patient population at Stanford, or about 1,000 patients per year.

In the Emergency Department, Stanford emergency physicians will continue to treat all patients, including MIAs. But MIAs who need hospital admission will be treated and then will need to be transferred to a county facility when their condition is stabilized and they can be safely transported.

According to Michael Eliastam, director of the Emergency Services, "conditions such as serious trauma, heart attack, or any other situation where immediate care is required, will certainly be treated at Stanford." However a patient who may need elective surgery, as for hernia repair, which is not an emergency, will be informed of the need for surgery or other care and will be advised to go to a county facility.

The change in law will affect approximately 270,000 Californians. For many it may mean changing the doctors and hospitals they have been accustomed to using.

According to the law, some persons in the MIA category will continue to receive Medi-Cal benefits after January 1 at whatever facility they or their physicians choose. These include individuals in skilled nursing or intermediate care facilities, medically indigent children, pregnant women, and refugees in the United States less than 18 months.

HEALTH INFORMATION: SEX AFTER A HEART ATTACK

STANFORD—

"The Loving Heart: Sex after a Heart Attack" is the topic of a program to be held 7-10 p.m., Thursday, Feb. 10, in the Sherman Fairchild Auditorium at Stanford University Medical Center.

Sponsored by Stanford Nursing Services, the workshop will attempt to provide factual information to health care professionals, increasing their ability to contribute to patient awareness and understanding.

A lecture-slide presentation will identify numerous myths associated with the subject, describe the phases of sexual activity, discuss various positions for sexual relations, and review medications and their effects on the heart and sexual functions.

Speaker for the program will be sexologist Richard Sharon, M.A., Ph.D., who has his doctorate from the Institute for Advanced Study of Human Sexuality where he studied under Dr. Wardell Pomeroy, co-author of the Kinsey Reports.

Sharon has published in the *Journal of the American Medical Association* and is the author of two books and numerous articles dealing with sex-related issues. Currently practicing in Burlingame, California, Sharon has completed a large research study on the effects of heart attacks on the sexuality of men, women, and their respective partners.

Fee for the course will be $5, which can be paid at the door, with an extra $10 for nurses who wish to receive continuing education credit. Net proceeds will go to the Friends of Nursing Scholarship Fund.

The program is open to the public. For further information, call Katherine Barnett, R.N., at (415) 494-8074.

THE STATE OF THE ART IN PLASTIC AND RECONSTRUCTIVE SURGERY

STANFORD—

Imagine a young man losing his arm in a car accident. So badly mangled, it cannot be surgically reattached. Instead, surgeons attach a new arm—received from a donor. With proper medication and physical therapy, the young man gains full use of his new limb.

Sound impossible? Not at all, predict leading plastic surgeons at Stanford University Medical Center. "We've got the technical know-how now," said Dr. Lars Vistnes, surgery professor and chief of the Plastic and Reconstructive Surgery Clinic. "As soon as we can overcome the immunological barriers, we'll be able to transplant limbs. It's the next big leap."

The "immunological barrier"—rejection of the limb—is being broken down, however, Vistnes adds, with the development and refinement of immunosuppressant drugs, such as Cyclosporine, which are used in heart and lung transplants.

"The reason we won't risk transplanting limbs and possible rejection by the patient is because a limb, unlike a heart or a lung, is not essential to sustain life," explained Dr. Robert Chase, surgery professor and head of the hand unit of the Clinic.

Powerful immunosuppressants always compromise the body's ability to fight off infections. Transplanting limbs, the surgeons believe, is not yet sufficient trade-off if the infection risks are high.

Vistnes and Chase are cautious, but optimistic about the future of plastics and reconstructive surgery. Their optimism is based on the recent development of techniques that have enabled their specialty to advance in great strides.

The two major developments in the last decade, Vistnes said, are the discovery that it is possible to move entire units of skin, based on the underlying muscles and blood supply, and microsurgery.

Until recently, Vistnes elaborated, surgeons thought skin could only be moved if the blood supply remained intact. For example, in order to graft skin from one part of the body to another, it was necessary to bind the two parts together, let the skin begin to grow on the new area while still being kept alive by its attachment to the original area, and then separate the two parts once again.

-more-

Now surgeons can completely remove a unit of skin and muscle from one area, and transfer it to a new area, without the two areas having to be physically attached to each other during the process.

"This discovery shortens the hospital time for the patient, cuts the number of operations to only one, allows the patient more comfort, and it doesn't ruin the site the skin is taken from," Vistnes explained.

What's more, he continued, it enables surgeons to do procedures such as reconstructing breasts on women who have had masectomies, and replanting patients' limbs that have been severed.

"For example," Vistnes said, "some time ago an Alaskan man caught his hair in a machine and his whole scalp was torn off. The man was flown down to Stanford, with his scalp in a bucket of ice. Dr. Vincent Hentz (associate professor of surgery) replanted it, and today he has a full head of hair. Ten years ago this wouldn't have been possible."

Not to be overlooked in the success of such procedures is the use of microsurgery techniques. With the aid of microscopes, surgeons can now see how to reconnect miniscule tendons, blood vessels, muscles, and other components of the body. This ability, Vistnes said, enables surgeons to "salvage severely mangled extremities that would otherwise have to be amputated."

"Microsurgery is the most dramatic technical advance in years because it allows surgeons to transfer parts of the body, including skin, bones, soft tissue, and entire parts from one place to another," said Chase. "What's also very exciting is the transfer of muscles, often from lower to upper limbs, to take over the function of muscles that have been lost."

Other advances in the area of hand surgery, Chase continued, include the management of fractures. "By using mini mechanical gadgets, such as pins and screws, to hold the fractures in place we can mobilize the hand immediately even though the bones are broken," he said.

This also cuts down on the length of time casts are used, if at all.

More implantable devices, such as artificial joints and bones, aid in the management of degenerative diseases, such as arthritis, Chase added.

Considered by many to be the "father" of hand surgery, Chase is also developing a computer image of the hand. By converting each component of the hand to a numerical formula, it will be possible to get a multidimensional image on a screen. By making all the components movable, Chase said, surgeons will be able to learn the biomechanics of the hand to aid them in managing hand injuries, and in building robotic hands.

Two-pound premature infants weren't struggling to stay alive in incubators when Marie Jorgensen became Stanford's first social worker in May 1913.

Jorgensen's duties, from the scanty records which remain, probably centered on ameliorating financial hardship and providing general hygiene information for about 1,000 patients that first year at Lane Hospital. That was Stanford's San Francisco teaching hospital before the medical campus moved to Palo Alto in 1959.

Jorgensen's formal career as a social worker began at Stanford only eight years after what is regarded as the nation's first Social Services Department was established at Massachusetts General Hospital in Boston.

Now it is 70 years later, and social workers Charlene Canger and Rose Grobstein bristle at the stereotype of a social worker—the smiling bearer in a wicker basket of goodies or money for the humble poor.

Although they often help families find financial resources, they said most of their work involves family issues which are changing as rapidly as science constantly pushes the state of medical technology.

In fact many of the most important changes have occurred not since Jorgensen rode in a carriage to work. Instead, the most dramatic years may have come between 1962, when Grobstein helped start the first intensive care nursery at Stanford, and the present when Canger is the fulltime social worker in the ICN under Grobstein's supervision.

Some of the changes will be discussed by Canger and child psychiatrist Charley Zenah at a seminar for ICN professionals scheduled at Stanford on Jan. 28. The seminar is part of a year-long celebration as social services at Stanford celebrates its 70th anniversary.

"The preemie babies of 1962 are not the preemie babies of 1983," says Canger.

"It used to be that babies were critically ill and then either died or got well quickly."

But now the babies are smaller, less developed, "and we are finding that they sometimes go from being acutely ill to a long period of chronic illness."

Although they are saved at a premature age and low birth weight that would have been inconceivable even five years ago, they go home with serious physicial problems which the family must deal with.

"We have to help the families go home with a greater degree of uncertainty . . . . The support which is needed is more extensive, and by necessity, our jobs become more complex, Canger continued."

"Nobody says life is fair," reads the sign in Grobstein's office. It's a summary of her battle for realism.

-more-

"Fairness is a real issue," interjected Canger. "You'd be surprised at the number of parents who say after the death of an infant: 'But I took such good care of myself.' Or sometimes they'll grieve that their baby is dead or deformed 'while that mother who didn't even want a child had a healthy baby.'"

Grobstein's battle to help patients deal realistically with issues began, she said, when she was a young social worker more than 40 years ago in the coastal hills of Oregon.

"I visited one particular family whose unclean house I thought might jeopardize the health of a newborn child. So another social worker and I brought cleaning materials up to their cabin one month and helped them clean up.

"When I returned a month later the place was just as dirty as before. It was then I realized that people had to do for themselves."

Helping patients and their families, Canger and Grobstein explained, is a major duty of the hospital's 21 social workers.

"But we also have a role at helping the other members of our teams—including doctors and nurses—cope with the stresses of the environment.

"In the ICN one recent week we had six (premature infant) deaths. The amount of stress this produced could have been intolerable for all of us. But we were able to talk."

Discussion among staff was begun in what ICN physicians and nurses have lauded as an innovative pilot program under Grobstein's direction in the mid 1960s.

A study was underway to learn whether contact between preemies and their mothers would foster bonding without being a safety risk.

Dr. Philip Sunshine, professor of pediatrics and director of the ICN, said the experiment produced some tensions and feelings of competition between the mothers and nurses, who previously had a "monopoly" on the infants' attentions.

Grobstein initiated frequent staff meetings for the nurses and doctors, a tradition which was expanded to deal with other tensions in the unit. These meetings continue today under the informal leadership of Canger.

Grobstein has left the ICN for a role as chief pediatric social worker but she still sees clients, among them participants in a genetic counseling program.

"That's an attempt to deal with problems before they appear in the nursery," Grobstein said.

Although terminating a birth is sometimes an option, Grobstein said her role can often be helping families to prepare for a birth where prenatal testing has revealed damage or a genetic defect.

Grobstein said she came to Stanford from a job with an adoption agency in San Jose "because I was looking for some answers. I wanted to do some research and the opportunity was here at Stanford."

Results of her subsequent research include more than 14 authored or co-authored articles and book chapters, as well as an appointment as a lecturer both in Stanford's Department of Family, Community and Preventive Medicine (FCPM), and at the School of Health and Medical Sciences at UC Berkeley.

(Editors:Please note sidebar on THE STATE OF THE ART IN PLASTICS AND RECONSTRUCTIVE SURGERY *mailed simultaneously with this story)*

CLINIC RELOCATES TO HOOVER PAVILION

STANFORD—

Stanford University's Plastic and Reconstructive Surgery Clinic has a new home at Hoover Pavilion as of Feb. 1, 1983.

The move, part of the Stanford University Clinics renovation project, consolidates the Clinic to allow patients to register, and receive treatment and therapy all in one area.

Hoover Pavilion is Stanford University Hospital's annex on Quarry Road and El Camino Real, Palo Alto.

"Our offices used to be in one place, our clinics in another, and our research laboratories in yet other place," noted Dr. Lars Vistnes, Clinic chief. "Now we have everything concentrated in one area to offer care more efficiently."

The new Clinic has access to two operating rooms for major operations, an outpatient minor operating room, available hospital rooms within the proximity, and laboratories in addition to larger examining rooms.

"We're gaining hours of availability in addition to space," Vistnes explained. "Before we had to share the rooms with other specialties. This is all ours."

Vistnes is also excited about the chance to offer patients increased continuity of care. Because of the proximity, the nurses in the Clinic will be able to see hospitalized patients as well, he said. Occupational and physical therapists will also be at the Clinic. "It will be more of a family affair," Vistnes concluded.

"We're quite excited about the move because it places us in direct relationship to inpatient and outpatient services, just one floor below the operating rooms, and near occupational and physical therapists," added Dr. Robert Chase, chief of the hand unit of the Clinic.

The Clinic is open from 8 a.m.-5 p.m. Monday through Friday. General plastics and reconstructive surgery patients should call 497-7001, and hand surgery patients should call 497-5256 for information and appointments.

HEALTH RESEARCH POLICY BUILDING TO OPEN

STANFORD—

Members of the Consortium for Health Research and Policy at Stanford will move to new headquarters in the campus building which formerly housed the Medical Microbiology Department, now located in the Fairchild Building. The move is scheduled for completion by Feb. 1.

In all, about 75 persons will be stationed in the renovated building. Designed by architect John Northway (of Stoecker and Northway, Inc.), the renovation is intended to give a physical boost to the concept of group health planning as conceived by the Consortium for Health Research and Policy.

Located at the north end of the Basic Sciences Building across Campus Drive from the Medical Center, the site had originally been a part of the Stanford Museum, until after the 1906 earthquake when it was approved by the Trustees for use by the basic medical sciences.

President Donald Kennedy now has approved a new name for the building, to be known henceforth as the Health Research Policy Building.

Among other renovations, the Schultz Auditorium has been remodeled for the academic functions to be housed in the building. Project manager for construction was David Jerome of University Facilities.

Included in the move will be the entire Department of Family, Community and Preventive Medicine, except for the Division of International Health.

Count D. Gibson, Jr., chairman of the department, explained that the two components until now housed at 703 Welch Road—the Division of Health Services Research and the Primary Care Associate Program—will be joining the rest of the department as a result of the move.

-more-

2-2-2

Director John Farquhar, Dr. Stephen Fortmann, and administrator Lillian O'Toole from the Stanford Heart Disease Prevention Program will also be moving with their office staffs to the renovated building.

Co-director of the SHDPP, Nathan Maccoby of Communications, along with the program's community education group, will move from their present location in Cypress Hall. And all SHDPP postdoctoral fellows, presently scattered at Cypress and throughout the Medical Center, will join the group as well.

(Drs. Peter Wood and William Haskell, and the rest of the SHDPP staff, will remain at 730 Welch Road.)

Drs. James Fries and Halsted Holman of the Division of Immunology will also be included in the move. Fries and Holman are responsible for the Stanford Arthritis Center, including the American Rheumatism Association Medical Information System. The Clinical Scholars Program, directed by Holman, will move as well.

About two years old, the Consortium is a group of Medical School faculty members joined with colleagues from other Stanford University departments to focus their separate research programs on issues of national health policy and service.

Research requirements in these areas include, in addition to medicine, a variety of social science skills, including economics, sociology, psychology and communications. Hence the renovated building will serve as an interdisciplinary research center.

The Board of Trustees approved the $1.5 to $2 million remodeling project in October, 1981, aiming to move many of the Consortium's key members into a single office complex.

HUMANISM NEEDS TO BE INCORPORATED IN MEDICAL EDUCATION, SYMPOSIUM CONCLUDES

STANFORD—

Getting humanism back into medical education was the key concept that emerged at a Stanford University School of Medicine symposium Jan. 22.

The symposium, which discussed aspects of the general professional education of the physician, was spurred by the Association of American Medical Colleges' ongoing national study of medical education in the United States.

Three panels, made up of faculty and students, considered separate aspects of medical education including essential knowledge, fundamental skills, and personal qualities, values and attitudes of physicians.

What panelists concluded is that humanism begins to be eliminated starting with the "pre-med syndrome" before students even start medical school.

Almost 90 percent of pre-medical students major in science, said Dr. Robert Cutler, professor of neurology and associate dean of medical education. "Is that emphasis necessary?" he asked.

"Students know what they need to get into medical school and that dictates the way they become," said Dr. Lawrence Mathers, pediatrics intern at Stanford University Hospital. "Until the admissions standards are changed to consider other qualifications besides facts and numerical scores, nothing will change."

"Medical school requirements should not interfere with students' undergraduate education," added Dr. Saul Rosenberg, professor of medicine. "Their education needs to be broad and diverse, including all areas and not just science. They do need basic scientific facts to be able to proceed with their medical education, but they don't necessarily need A's in those courses, nor do they need to get involved in other activities such as research or hospital work.

"Students coming into medical school know lots of facts," continued Rosenberg, who took a year-long sabbatical to research the problems of premedical students competing to get into medical school. "But they are deficient in other skills such as communication, observation, problem-solving, and judgement-making. These are the skills involved in everyday practice as a physician, not the facts.

"Premedical students are too concerned with their grade point averages, and come out too narrow minded," Rosenberg concluded. "Premeds who are nerds become medical students who are nerds become doctors who are nerds and parents and spouses who are nerds."

-more-

The lack of humanism is apparent in the admission procedures as well as requirements, Mathers added. "It's impossible to find out if a student will be a good doctor on the basis of an hour-long interview. And Stanford, having incorporated a computer to do preliminary screening of applicants, is moving towards a more mechanized, less personal admissions approach."

The lack of humanism continues once the students get to medical school, panelists noted, in the manner that fundamental clinical skills are taught. The physician-patient relationship needs to be nurtured in courses, said Aria Dibiase, third-year medical student."Students don't get enough preparation in these skills. On their clerkships they have the most responsibility to talk with the patients. There is a lack of good role models. Students need to be taught how to be educators and communicators as part of being a physician," she added.

"The clinical experience always starts with an introduction, taking the history, having the patient disrobe and doing the physical exam. At the end of this initial encounter the physician can tell the patient what to do," said Dr. Mark Perlroth, associate professor of medicine. "A special bond needs to be created between patient and physician in order to be effective. Without it, everything else—knowledge, facts—is useless."

Dr. Edward Shortliffe, assistant professor of medicine, stressed the need for medical students to become familiar with computer technology because of its increasing use in medicine. "Students and physicians need to be familiarized with computers or they will be disinfranchised from the practice of medicine," he predicted.

In response to criticism that computers would make medicine even less personal, Shortliffe argued that the time saved by using computers would, in fact, give physicians more time to spend helping their patients adapt emotionally to their conditions.

Dr. Harold Sox, Jr., associate professor of medicine, stressed the need to educate students in clinical decision-making as another fundamental skill. "Students are not being adequately prepared for today's situation of limited resources. They need to be encouraged to make decisions that will allow them to give the highest quality of care for less cost," he said.

Rather than concentrate only on what students need to be taught, said Dr. Kelley Skeff, assistant professor of medicine, the method of teaching should also be considered. "We need to consider the skills and approaches of individual teachers, and the effect on learners," he said.

"With increasing emphasis on attracting a diverse group of learners, we need to diversify teaching methods because everyone does not respond the same way. We need to assist the faculty by creating an environment in which their individual traits, such as humanism, can be brought out to the utmost."

-more-

3-3-3

Perhaps the ultimate area in which humanism is ignored, panelists contended, is with the medical students themselves.

"About 26 percent of the fourth-year medical school class is in counseling at Cowell Student Health Center," said Dr. Harvey Weinstein, assistant clinical professor of psychiatry. He identified medical students' greatest problems, as depression, lack of self-concept and anxiety, and education's impact on personal relationships.

"Physicians take on a great deal of responsibility for society's characteristics, and for having mass amounts of knowledge. They are constantly performing—in school, on hospital rounds—and are always under scrutiny. They are taught to put their own needs last, and are encouraged, and rewarded, for ignoring time," he explained."There's a discrepancy between physicians' caring for others and caring for themselves.

"My concerns about medical education," Weinstein continued, "are that it doesn't teach students to learn about feelings, and it doesn't give them time to assimilate feelings and experiences and to deal with personal problems. This attitude—humanism—needs to be built into the curriculum, and the faculty has to be taught how to teach it."

"We act as though our patients have no needs of us other than an accurate diagnosis and a treatment," summarized Dr. Allen Barbour, Medical School ombudsman. "We act as though our feelings will simply get in the way of our more important cognitive judgements and that it is okay to ignore the human condition and problems of our patients and each other.

"The main impediment to the growth of these desirable traits in our students is our total emphasis on facts, figures, techniques, and academic excellence combined with a corresponding exclusion of caring, understanding, empathy, collaboration, feelings, or an honest awareness of all that is human in our interactions. We could make a big step forward by affirming these qualities clearly as ideals; by looking for them in admission interviews; by practice in our interactions with patients, students, and all others; and by active discussion at rounds and other opportunities."

SHORTLIFFE NAMED KAISER FACULTY SCHOLAR

STANFORD—

Edward H. Shortliffe, assistant professor of medicine and computer science at Stanford, has been named a Henry J. Kaiser Family Foundation Faculty Scholar in General Internal Medicine.

The foundation said the award provides a $50,000 annual grant for three years, with an option by the giver to renew for two more years. The annual grant includes $35,000 for salary support and $15,000 in unrestricted funds to support research.

The primary research effort of Shortliffe— one of four academic physicians nationwide to receive one of this year's Kaiser grants—is the the SUMEX-AIM Computing Resource, which is develping computer systems to aid physicians make difficult and sophisticated diagnoses of patients. Shortliffe is the chief physician scientist on the project.

The holder of both a Ph.D. in medical information sciences (computers) and an M.D. from Stanford, Shortliffe recently spearheaded the creation of a graduate program integrating medicine and computer science.

Other recipients this year—the third Kaiser has awarded the five-year honor—are Randall D. Cebul, the University of Pennsylvania, Philiadelphia; Mark R. Cullen, Yale University, New Haven, Conn.; and Daniel E. Singer, Harvard University, Boston.

The Stanford recipient joined the faculty in 1979 as an assistant professor.

The foundation, based in Menlo Park, Calif., was founded in 1948 as a charitable trust by the late industrialist Henry J. Kaiser.

In 1982, the foundation authorized grants of more than $15 million to support efforts in the field of medicine and health.

DIABETIC VOLUNTEERS NEEDED

STANFORD—

Are high carbohydrate diets really effective in controlling diabetes?

Volunteers are needed to help answer this question by participating in research conducted by Dr. Gerald Reaven and associates at the clinical research center at Stanford University Hospital.

To be eligible for this study, volunteers must have non-insulin treated diabetes; be currently treated by diet or oral agent; be between 20 and 69 years old; and be otherwise in good health.

Participants will be offered the following free of charge: evaluation of blood sugar, insulin, lipids (cholesterol and triglycerides), routine health evaluation including liver and kidney function test, cardiogram, physical exam, dietary evaluation and meals during the entire study.

Anyone interested or wishing further information should call Dr. Clarie Hollenbeck or Dr. George Liu at (415) 497-6973 between 9 a.m. and 5 p.m., or Ann Coulston, R.D., at (415) 497-5430 between 9 a.m. and 12 noon.

PSYCHIATRISTS DISCUSS ANXIETY DISORDER TREATMENTS

STANFORD—

Psychiatrists have come to agree that anxiety disorders, such as claustrophobia, fear of heights, or agoraphobia, are not merely symptoms of other diseases as was once thought, but rather are separate diseases.

They also agree that separate treatments are necessary to treat anxiety disorders, and in the last decade or so several have been developed.

What the psychiatric community does not agree on is which of these treatments is the most effective. Some of psychiatry's leading authorities shared their experiences with their preferred treatments—behavior therapy, drug therapy, or psychotherapy—at a recent symposium at Stanford University.

Anxiety disorders, or phobias, are triggered by events coming from within the patient, such as fear of eating solid food; or from outside the patient, such as fear of snakes.

What starts out as a simple fear may develop into a severe disease, said Dr. David V. Sheehan, Harvard assistant professor of psychiatry and director of the Hypnosis and Psychosomatic Medicine Unit at Massachusetts General Hospital.

A patient may start out experiencing dizzy spells, for example, he explained. These dizzy spells become more concentrated, eventually causing the patient to become hypochondriacal. They often attach that hypochondria to a concrete situation, such as a simple phobia. 'I'm feeling dizzy,' the logic goes, 'because of my fear of spiders.' This simple phobia, fear of spiders, may expand to social phobias, fear of groups, to agoraphobia and multiphobias. The end stage is often depression, Sheehan continued, which can result in suicide.

Becuase of this progression, anxiety disorders need to be treated.

"Many patients think they're the only ones with these fears," said Dr. Walton T. Roth, associate professor of psychiatry and chief of the Psychiatric Consultation Service at the Palo Alto Veterans Administration Center. "They think they are just disasters. They're relieved when the find out this isn't so."

Treatments have developed in three major areas. Dr. W. Stewart Agras, professor of psychiatry and director of the Behavioral Medicine Program at Stanford, said research shows behavioral therapy is effective in treating anxiety disorders. Systematic desensitization—having patients imagine the phobia until they learn to relax—is more effective than the more traditional psychotherapy, he said. Implosion therapy—having patients start off in the worst possible situation—is also effective.

The best behavioral therapy treatment, however, is exposure to the feared situation, Agras' research showed. Exposure increased the time the patients were able to spend in the situation. Their heart rates decreased also, proving that the longer patients were exposed to the situation, the more comfortable they grew to feel.

Behaviorial therapy combined with drug therapy—anti-depressant drugs specifically—had even better results, Agras continued.

"By themselves, the drugs have little effect. But the combination with behavior therapy has a great effect," he said.

"The active ingredient in behavior therapy is that it is real life," Sheehan conferred.

Dr. Alan Skolnikoff, associate clinical professor of psychiatry at University of California, San Francisco and training and supervisory analyst at San Francisco Psychoanalytic Institute, however, said psychotherapy is the desired treatment for most phobias. "The phobia is just a cover up for a much larger anxiety," he explained. "Uncovering that anxiety through psychotherapy cures the phobia in the process."

Skolnikoff advocated transcendental meditation and other relaxation techniques also as anxiety-reducers.

Dr. Robert E. Fowles, assistant professor of medicine and director of the Noninvasive Cardiovascular Laboratory at the VA, brought up another controversial issue. Whether mitral valve prolapse is a symptom or a cause of anxiety disorders has been questioned since the condition was first diagnosed among soldiers in 1871.

Mitral valve prolapse is a condition in which the valve regulating blood flow between the left ventricle and left atrium fails to do so efficiently. This causes a backflow of blood in the heart, which in turn may cause circulatory problems.

It may cause 'funny sensations' that may cause anxiety among patients, he said, but research at Stanford has shown that the presence of mitral valve prolapse is not necessarily connected to anxiety disorders.

"It doesn't matter what anxiety disorder treatment is used, just so the patients get better," Sheehan concluded. The physicians' treatment should aim to get rid of the immediate symptoms with medication; eliminate the phobic behavior with behavior therapy; eliminate any underlying causes with psychotherapy; and finally encourage long-term control of the phobia with patient education, he said.

HOSPITAL PLANS WAYS TO CUT STAFFING COSTS

STANFORD—

Guidelines to reduce staffing costs, such as temporary reductions in workdays or reduced work weeks, were outlined to Stanford University Hospital department heads Tuesday, Jan. 18.

No employees are being laid off their jobs at this time. "We want to do everything possible to avoid layoffs," said Sheldon S. King, executive vice president and director.

Cost reductions are necessary because of low patient census during the past few months, said King. He cited the distressed economy as a cause of the low census. With high unemployment rates, more people are delaying elective procedures and keeping hospital stays to a minimum.

Hospital use throughout California has been dropping steadily since 1980, according to a recent quarterly report by the California Health Facilities Commission. The number of patients discharged from hospitals in Santa Clara County was down 3.3 percent in October 1982, compared to the same quarter in 1981, and the number of patient days of care was down 9.0 percent.

Because of reduced needs, some patient care units at Stanford have been closed and staff asked to take an extra day off periodically.

The new staffing guidelines are not related to whether the hospital receives a contract from the state to treat Medi-Cal patients. The hospital is still waiting to hear whether or not a contract will be awarded to Stanford. In the meantime, the hospital is continuing to admit authorized Medi-Cal patients.

More severe cost reduction measures may be considered in the event the hospital does not receive a Medi-Cal contract or if low census figures continue, King said. In that case, administrators would try to set a specific monetary goal for reductions.

The hospital employs 4,497 people, including more than 1,400 nurses.

Some hospital departments, such as nursing, housekeeping, respiratory therapy and others have staffing cost reduction plans already working. Some nurses, for example, have been asked to take one day off each month. The new guidelines are meant to assist department heads throughout the hospital in examining and dealing with alternative ways they can reduce staffing as they consider appropriate to their area.

-more-

In some departments, employees may be asked to take reduced workdays on a temporary basis. In other departments reduced workweeks might be recommended.

Before reduced workweeks are put in effect in a department, said King, affected employees will be given at least two weeks written notice. They would be able to use Paid Time Off (PTO) or Absent Time (time off without pay) to cover the days reduced from their previous schedule.

At this time, employees whose hours are reduced will still remain eligible for benefits, even though their hours may fall to less than the 50 percent benefit requirement.

Department heads will work with their line administrators and the Director of Personnel before any plans are presented to employees.

Other alternatives, which will be evaluated by individual departments and implemented on an as-needed basis, include:

- extending the period that jobs are held open before authorization to hire is given. Job vacancies are now held open for 30 working days. The new guidelines call for an additional 30 calendar days vacancy period;
- increased scheduling of PTO or Absent Time before a shift is completed, releasing employees from their jobs early;
- contacting employees at home if it appears at the start of a shift that the full amount of scheduled staff will not be needed.

In all of the alternatives, employees would be asked to voluntarily participate, depending on the department's needs. If there are not enough volunteers, then there may be mandatory reductions, based on seniority, which may ultimately affect all employees.

STANFORD UNIVERSITY MEDICAL SCHOOL COURSE HELPS STUDENTS DEAL WITH STRESS

STANFORD—

Teaching students how to face the stress and strain of modern medical education is now part of the curriculum at Stanford University School of Medicine.

Everyone is aware of the varying degrees of tension that afflict medical students, interns, and residents. And much has been written about medical training's impact on their well-being, including depression, dehumanization, stress, anxiety, cynicism, and even suicide.

What is new is that a few schools—including Stanford—are beginning to offer students information about and ways to alleviate potential problems as part of the curriculum. A ten-week course entitled *The Human Costs of Medical Education* offers students and Stanford University Hospital housestaff the opportunity to discuss what they're going through with classmates and professionals.

"The course lets students know they're not the only ones going through tough times and that it is all right to feel what they may be feeling, what they may go through farther along in their training, and ways to cope with potential problems," said Dr. Harvey Weinstein, clinical assistant professor of psychiatry.

Weinstein coordinates a faculty of 13 who contribute to the course. The faculty consists not only of physicians, but sociologists and anthropologists as well. "I've never seen so much cooperation and effort go into planning a course," Weinstein noted.

The course, offered once each academic year, is run informally, with lots of discussions, panels, and sharing of experiences and feelings. The weekly sessions take on themes such as "The Formation of a Physician Identity", "Learning from Physicians","The Emotional Costs of Patient Care", "The Benefits of a Medical Career Choice", "Life Beyond Medicine: The Effects of Medicine on Personal Relationships", "Institutional Constraints, Traditions, and Individual Response", and "The Winds of Change: Political Aspects of Care, and Change in Culture".

-more-

The course was formed one year ago when its need was identified by the Medical School's Committee on Well-being for Medical Students and House Staff (CWBMS). CWBMS, made up of students, housestaff, and faculty, was established in 1978 to assess the problems and needs of students and housestaff, and to recommend and institute appropriate programs.

Weinstein, who counsels many medical students as part of his practice at Cowell Student Health Center, said they are mostly affected by their inability to cope with the demands of medical school, and the impact those demands may have on their personal relationships.

"Most medical students don't have the time to assimilate what's happening to them," he explained. "They develop the process of not talking about it to their spouses or friends. This causes them to become alienated. They learn to ignore their own and their families' interests and needs."

If medical students develop these habits early on, Weinstein concluded, they can develop into more severe distress, and often impairment such as alcoholism or drug addiction.

For more information, call Dr. Weinstein at 497-3785, or the Office of Student Affairs at 497-6951.

GENETIC PATENT ROYALTIES TO FUND POSTDOCTORAL FELLOWSHIPS

STANFORD—

Royalties awarded to Stanley N. Cohen, professor of genetics, for his role as co-inventor of specific gene splicing and cloning methods, will be pumped back into education to fund fellowships for young scientists, Dominick P. Purpura, Dean of the Stanford School of Medicine, announced today.

Named the "Bernard Cohen Fellowship Fund," in memory of Cohen's father, the initial contribution of more than $150,000 is the beginning of an endowment intended to "provide long-term support for postdoctoral trainees at Stanford," Cohen said.

"One of the greatest needs in any area of science today is to support the training of young scientists," he said. "With the cutback in federal funds for training purposes, that need has become especially acute in recent years."

Postdoctoral students from throughout the School of Medicine and Department of Biology will be eligible to apply to the Fund, which will be administered by the Dean's Fellowship Fund committee.

To date, $1.4 million in gross revenue has accrued from the 73 genetic engineering firms licensed to use techniques described in the first Cohen/Boyer patent, which was issued in December, 1980.

Cohen's personal share of this revenue constitutes seed money for the endowment.

The patent covers fundamental techniques that Cohen and Herbert W. Boyer of the University of California, San Francisco developed to rearrange the genes of common bacteria.

By inventing ways to replicate genes that code for desired traits within microorganisms, Cohen and Boyer developed a powerful tool for investigating the organization and function of genes.

The techniques also made possible the construction of "bacterial factories," new sources of such medically useful, but difficult to obtain products as insulin, human growth hormone, and the anti-viral drug interferon.

The United States Patent Office has not yet approved a second Cohen/Boyer patent, which would license the intermediate products of the techniques.

But the revenues used to set up the Bernard Cohen Fellowship Fund will not be affected by the Patent Office's ultimate decision on the second patent, according to Niels Reimers, director of Stanford's Office of Technology Licensing.

Born in Perth Amboy, New Jersey in 1905, Bernard Cohen was a merchant with "a great deal of interest in science," according to his son.

"He was a remarkable man and an inventor of sorts," Cohen said. "I wanted to honor his memory."

NIH BIOMEDICAL RESEARCH GRANTS AWARDED

Details follow asterisks

STANFORD—

The molecular biology of sleeping sickness, effects of psychological stress on the immune system, and the physiology of epilepsy are among the newly funded research topics of ten young scientists at the Stanford University School of Medicine.

Each researcher was awarded a $5,000 allocation January 1 from the Biomedical Research Support Grant, provided twice each year by the National Institutes of Health, and administered by a Stanford faculty committee.

The grant is designed to help young scientists establish research programs in areas of basic and clinical research.

The ten assistant professors awarded one-year grants are: John C. Boothroyd (medical microbiology), Christopher L. Coe (psychiatry), Barry W. Connors (neurology), Kevin Fish (anesthesia), Andrew Hoffman (medicinendocrinology), Fredric Kraemer (nephrology), Fred Mihm (anesthesia), Edward S. Mocarski (medical microbiology), Jane Parnes (medicinemmunology), and Paul Ponganis (anesthesia).

* * * * *

Boothroyd will use his grant to study African trypanosomes, parasites that cause "sleeping sickness" in humans. A large part of the organism's ability to cause disease is linked to its talent for altering the proteins that stud its membrane coat. Boothroyd is studying the genes that control the changing protein pattern.

Parnes, too, is studying genes, this time as they relate to the human immune system. The several classes of "T-lymphocytes," white blood cells that control the immune system, have unique functions that may be associated with their protein coats. Parnes will investigate the role the proteins play in enabling the T-cells to do their work in battling infection.

-more-

Coe will study immunity from a different angle: the effects of psychological stress on immune responses. "Although it is generally acknowledged that stress can compromise resistance to disease," Coe said, "further investigation is still needed to determine how different types of stress affect specific aspects of immune responses."

Epilepsy is the target of Connors' research. Large bursts of electrical activity in the brain signal an epileptic seizure, but between seizures, small abnormal discharges of electricity are often detected in the nerve cells of persons with epilepsy.

Connors will study these small events to capture a more detailed picture of the electrical and chemical disturbances that underly epilepsy.

Kraemer is investigating the way hormones regulate atherosclerosis, a clogging of the arteries with fatty plaques. Mocarski is studying the replication of DNA in cytomegalovirus, a variety of herpes virus that can be life-threatening in persons with a suppressed immune system.

Finetuning respiratory therapy is the goal of Mihm's research, as he studies a new method of monitoring the levels of oxygen in a patient's blood.

Fish will focus on the effects of the common anesthetic "halothane" on the metabolism of other drugs often given during anesthesia.

The effects of several anesthetic agents on the ability of muscle to contract will be the subject of Ponganis' research. Studies of postoperative patients indicate that volatile anesthetics can, in a few cases, trigger a disease known as malignant hyperthermia, in which the contraction of certain muscles is uncontrollable, and the subsequent rise in body temperature can kill the patient. Ponganis aims to elucidate the mechanism of the interaction between the anesthetic and the muscle.

Hoffman will study three chemical messengers in the brain (epinephrine, corticotropin releasing factor and vasopressin) as they interact to influence the output of the pituitary gland. Hoffman said he is especially interested in the pituitary because of the hormones it activates during periods of stress.

BULIMICS NEEDED TO JOIN STUDY AT STANFORD

STANFORD—

Volunteers are needed to participate in a study being conducted at Stanford's behavioral medicine clinic, to determine the relative effectiveness of two approaches in the treatment of bulimia—the binge/purge eating disorder.

"We've already seen positive results with the use of group therapy sessions," said Dr. Betty Kirkley, postdoctoral fellow. "Based on those results we're conducting this study, to test two variations of group therapy."

The first treatment groups are already under way, and the next ones should start in about a month and a half, said Kirkley, who needs to hear from potential participants as early as now.

Free treatment for bulimia will be provided to women between the ages of 18 and 49 who binge eat and vomit afterwards. The treatment program will consist of 16 weekly group therapy sessions, with seven people in each group.

Before entering the program, participants will be required to have a thorough medical examination. They will complete questionnaires at the beginning and end of the program.

For further information call Kirkley, at (415) 497-~~5868.~~ 7871.

COHEN OF VANDERBILT TO GIVE PUBLIC LECTURE

STANFORD—

"Epidermal Growth Factor" is the title of the ninth Windsor C. Cutting Memorial Lecture, to be held 4:15 p.m., Thursday, Jan. 20, in the Fairchild Auditorium at Stanford School of Medicine.

The public lecture will be given by Dr. Stanley Cohen, of the department of biochemistry at Vanderbilt University School of Medicine. His presentation is sponsored by Stanford's department of pharmacology.

Cohen is a pioneer in researching hormones which promote the growth of different types of cells, according to Dr. Tag Mansour, professor and chairman of pharmacology. Studies of these hormones lend insight into the control of the growth of normal cells and are hoped to further an understanding of the abnormal growth of cancer cells.

Cohen was co-discoverer of the first factor implicated in the growth of the nervous system in mammals (the "nerve growth factor"), said Mansour. He recently discovered the epidermal growth factor, and is actively engaged in identifying its mechanism of action in cell cultures.

Mansour said that eventually many more of these factors may be discovered. "Cohen's work represents a very important start in the area of the development and differentiation of cells," he said. "His research on the growth and development of mammalian cells may lead us to a rational approach in finding the origin of cancer."

A graduate of Brooklyn College, Oberlin College, and the University of Michigan, Cohen has published widely and been the recipient of many awards. These include the National Paraplegia Foundation's William Thomson Wakeman Award, the H.P. Robertson Memorial Award from the National Academy of Sciences, and the General Motors Cancer Research Foundation's Alfred P. Sloan Award.

He is a member of the National Academy of Sciences and has been an American Cancer Society Research Professor of Biochemistry.

The Windsor Cutting Lectureship was established in 1973 by the faculty of the Department of Pharmacology, and is supported by private contributions. It honors the memory of Dr. Cutting, professor and former chairman of the department.

Cutting, who died in 1972, also served as dean of Stanford Medical School from 1953-57, and as dean of the University of Hawaii Medical School, 1963-71.

The lectures are presented by speakers prominent in the field of pharmacology, and they are open to the medical community and to the public.

COMMITTEE CHARGED WITH MONITORING QUALITY OF CARE AT STANFORD UNIVERSITY CLINICS

STANFORD—

A committee to provide for communication, coordination, and quality control has been formed at the Stanford University Clinics, announced Dr. Lawrence G. Crowley, president of Stanford University Hospital.

The Professional Practice Committee, including physician representatives from each clinic, will function as "somewhat of a board of directors for the Clinics," said Chairman Dr. Ron Merrell, assistant professor of surgery. It has the authority to govern the Clinics under the general guidelines approved by the Executive Board, according to Don Tower, Clinics director. Its responsibilities include ensuring the quality of patient care, recommending policies and procedures for patient care, recommending appointment of physicians to the Clinics staff and responding and acting appropriately to patient complaints.

"The Clinics represent a large group of multidisciplinary physicians," Merrell noted. "We've never had a great deal of coordination among the physicians. Now with the renovation project underway, it's a good time to coordinate the physicians in their efforts to ensure superior care and patient satisfaction."

"The Committee illustrates our commitment to assuring Clinics patients the most effective, high quality health care," said Tower.

Committee members will be appointed annually, Crowley explained. They will serve on various subcommittees—each responsible for part of the Committee's charge as a whole—including the ancillary, medical records, policy review, and Boswell (Clinics renovation project) subcommittees.

"We wanted the Committee to include active physicians that are deeply involved with the Clinics and familiar with their operation. This is a unique opportunity for them to determine the structure for the future," Tower said.

The Clinics receive about 135,000 patient visits annually, and provide outpatient care by fulltime university faculty members. The Clinics are undergoing a $6.5 million construction, equipment, and remodeling program, scheduled to be completed in 1985. The renovation includes increasing the size and number of clinics and providing for a larger outpatient pharmacy and decongested corridor traffic.

Editors: This information is released jointly by the Palo Alto Medical Foundation and Stanford University Hospital. You are invited to attend the program. A descriptive flyer is available on request.

STANFORD—

"Medical and Health Care Uses of Cable Television," a community conference designed for physicians, nurses, and other health professionals, will be held Saturday, Jan. 29, from 8:30 a.m. to 1 p.m. in the Palo Alto Medical Foundation Auditorium, 920 Bryant Street.

The conference, which is open to the public, is sponsored by the Palo Alto Medical Foundation and Stanford University Hospital. It is coordinated by the Peninsula Community Access Television Association.

Applications of video and cable television in the health care field include education, clinical research, computer data banks, and internal communications, according to Robert Hecht, Stanford division coordinator of Instructional Media in the Medical Center. Hecht and Michael Yonchenko, Stanford audiovisual director and producer, will present the introductory remarks for the program. Potential uses include video teleconferencing among hospitals, nationally and locally produced health programming, staff training, and a variety of informational uses.

According to Tony Browne, assistant director of Public Information with the California Hospital Association, more than 300 cable systems are serving nearly 2.5 million subscribers in California. The cable companies feed signals from traditional broadcasters and the special cable network companies. With the technological improvements and more public awareness, cable franchise agreements with cities and counties are including more community services, such as public access and dedicated channels for special community interests. At Stanford, the University's Cable TV Steering Group, headed by Associate Provost Michael Oman, is working with Palo Alto officials on plans for cable services.

At the conference, Browne will discuss community involvement in the cable franchise and refranchise process.

Speakers also include David Watts, associate professor of Medicine, University of California, San Francisco, who produces the KQED television and radio "Health Notes" program.

Tom Rasmussen, director of satellite operations for the Hospital Satellite Network in Los Angeles, will discuss programming via satellite to health care professionals.

Tom Clayton of Peninsula CATV will moderate a panel discussion with questions from the audience. A complimentary lunch will follow the program.

There is no charge for the conference, but reservations are required because of limited space. Reservations may be made with Carroll Harrington of Peninsula CATV, 348 Waverley St., Palo Alto, 94302, or call (415) 326-0882.

LAW GRANTS ACCESS TO MEDICAL RECORDS

As a result of a new California law effective January 1, Stanford University Hospital patients and former patients now have access to the information in their medical records.

The law guarantees all patients in California the right to inspect or receive copies of their medical record information. Physicians have the alternative to provide a written summary of the record and assume the responsibility for preparing it.

Advance written request and payment of fees is required.

According to the law, requests for inspection must be granted within five working days after receipt of the written request. Requests for copies of the record must be granted within 15 calendar days. If a summary report is prepared, it must be available within 10 working days or 30 calendar days if the patient has been discharged from the hospital within the previous 10 days, or if the record is lengthy.

At Stanford, forms to request medical record information are available from the Dept. of Medical Records. Information is available from that office only during regular business hours, 9 a.m. to 4 p.m., Monday through Friday. Charges, to be paid in advance, are for clerical services, copying and mailing. The physician may also charge for the time spent in preparing a summary alternative.

Because many medical records are lengthy, patients may limit their request for copies to specific items that meet their needs.

Medical Records personnel will not attempt to explain or interpret anything in the record. Patients will be directed to their physician or other health professional for assistance in understanding the information contained in the record.

Access is granted only to living adult patients, unless there is a conservatorship of the person. Then the conservator has the right of access as the patient's representative. If the patient is a minor, the parent or guardian has access unless the minor had the right of consent to the treatment given.

There are special requirements relating to the release of information from psychiatric records or alcohol and drug abuse records.

The Hospital and physicians will continue to furnish information necessary for continuing a patient's care when it is requested by another physician or hospital, and consented to by the patient. Normally, insurance companies, schools, employers or other third parties who need information for a record request it directly, with the patient's written consent.

Questions concerning medical record access should be directed to the Correspondence Section, Medical Records Department, at (415) 497-5418.

NATIONAL STUDY SPURS STANFORD SYMPOSIUM ON M.D. EDUCATION

STANFORD—

A day-long symposium to discuss aspects of the general professional education of the physician will be held Saturday, January 22 at the Stanford University School of Medicine.

The purpose of the meeting is to generate ideas that might be useful to a national study of medical education in the United States now conducted by the Association of American Medical Colleges (AAMC), according to John W. Steward, associate dean.

The symposium, chaired by Dean Dominick P. Purpura of the medical school, will be held from 8:30 a.m. to 1 p.m. in Fairchild Auditorium. It will consist of three panels, each dealing with a specific aspect of medical education.

A panel, led by Dr. Robert Cutler, associate dean for medical education, will address these issues: promoting broad baccalaureate education, essential biomedical science knowledge, and teaching of essential concepts in medicine.

A second panel, chaired by Dr. Roy Maffly, chairman of the Medical School's admissions committee, will review the development of clinical skills during medical school and the acquisition of computer technology skills by medical students.

Dr. Steward's panel will examine personal qualities, values and attitudes of medical students, as well as the problems of students in dealing with emotional stress.

The AAMC-sponsored national study will be conducted by an 18-member panel of administrators and medical educators. Dr. Steven Muller, president of Johns Hopkins University, chairs the panel. The three-year project, the first such a comprehensive review of medical education since 1932, is jointly funded by the Henry J. Kaiser Family Foundation of Menlo Park, and the AAMC, which represents 127 medical schools in this country and 16 in Canada.

The review is necessary, the panel recently stated in an overview paper because since 1932, the purpose of the educational program leading to a medical degree has changed.

"Specialization and the rapid rate of advancement of knowledge and technology," the panel said, "may tend to pre-empt the attention of both teachers and students from the central purpose of medicine, which is to heal the sick and relieve suffering."

The 60-page overview paper, along with a questionnaire, has been distributed to medical educators and students in the United States and Canada.

The AAMC panel plans to hold regional hearings for the purpose of allowing medical school administrators, faculty, students and others to present views. Results of the Stanford symposium will comprise part of Stanford's contributions to the regional proceedings.

The first regional meeting has been scheduled January 27-28 at the University of California in San Francisco. Other hearings will be held in various part of the country through May 1983.

The final project report will be presented at the annual meeting of the AAMC in November, 1984.

ORTHOPEDIC SURGEON DIES

STANFORD—

Dr. Cly Howard Hatcher, professor of surgery emeritus and former chief of Stanford University School of Medicine's division of orthopedic surgery, died Dec. 29 at Stanford University Hospital from a massive heart attack. He was 82 years old.

Hatcher came to Stanford in 1960 after 30 years on University of Chicago's faculty. Following his retirement in 1965, he served as a consultant at Stanford and Palo Alto Veterans Administration Medical Center, and had a private practice in orthopedic surgery in Palo Alto.

He was a member of numerous professional societies, including the American Academy of Orthopedic Surgeons, the American Orthopedic Association, and the American Medical Association. He was an honorary fellow in the British Orthopedic Association, and served as a orthopedic consultant to the United Nations Relief and Rehabilitation Administration in Greece in 1946.

Hatcher received his bachelor's degree from University of California, Berkeley, in 1924, and his medical degree from University of California, San Francisco in 1929. He did postgraduate work in pathology at University of Innsbruck, Austria. His special interest was in bone diseases, especially tumors of the bone.

Hatcher is survived by three children: Barbara Ann of San Francisco; Nancy Hope Kagan of Chicago; and Henry Clark of Belmont. He is survived by two grandchildren as well. His wife, Annabel Clark, died in 1980.

Memorial services were held Jan. 3. Contributions can be made to the C. Howard Hatcher Memorial Fund at Stanford University.

ANXIETY DISORDERS SYMPOSIUM

STANFORD—

Anxiety disorders, such as claustrophobia, fear of heights, or agoraphobia, used to be considered symptoms of other diseases by the psychiatric community.

In recent years, however, psychiatrists have come to understand them as separate diseases, and have developed therapies with which to treat them. Stanford University School of Medicine's Department of Psychiatry and Behavioral Sciences is sponsoring a one-day symposium reviewing these developments Saturday, January 15, 1983.

Psychiatrists are now using new behavior therapy treatments, in which they help patients confront their fears, said Dr. Walton T. Roth, associate professor of psychiatry at Stanford and chief of the Psychiatric Consultation Service at the Palo Alto Veterans Administration Medical Center (VA).

Antianxiety drugs are being refined in ways to allow their usage for specialized therapies also, Roth added, thus providing for another treatment method.

Discussing all aspects of anxiety disorder characteristics and treatment will be some of ychiatry's leading authorities, including Drs. W. Stewart Agras, Stanford professor of psychiatry and ector of the Behavioral Medicine Program; Philip A. Berger, Stanford associate professor of psychiatry and director of the Stanford-VA Mental Health Clinic Research Center; Robert E. Fowles, Stanford assistant professor of medicine and director of the VA's Noninvasive Cardiovascular Laboratory; Leo E. Hollister, Stanford professor of medicine, psychiatry, and pharmacology and director of the VA's psychopharmacology research; Mardi J. Horowitz, University of California, San Francisco professor of psychiatry and director of the Center for the Study of Neuroses, Langley Porter Psychiatric Institute; and David V. Sheehan, Harvard assistant professor of psychiatry and director of the Hypnosis and Psychosomatic Medicine Unit at Massachusetts General Hosptial.

Discussion promises to be stimulating, Roth said, since the speakers differ in their belief of which method of treatment is most effective.

The course, which will be held at Tresidder Memorial Union on the Stanford University campus, will provide continuing education credit for physicians. Tuition is $60. Residents, interns, and medical students will be charged $10. For more information, call 497-5594.

NURSES HELP CUT HOSPITAL COSTS

STANFORD—

The surgery unit gives out the "golden towel award". Other units post lists of supply costs on the wall. And still others post graphs showing supply usage. Stanford University Hospital nurses are going all out in their efforts to cut expenses as part of a Hospital-wide cost-containment program.

"Cost-containment has permeated every unit. It's the byword now," said Joyce Miller, associate director of nursing. "We're not decreasing the quality of patient care at all, but we want to make sure we're doing all we can to cut costs."

The nurses' greatest effort has been in using linen more efficiently, Miller said. Their goal is to decrease the amount used for each patient by two pounds from the 1982 average of 21 pounds per patient each day. This alone will save the Hospital $150,400 each year in laundry services, she explained.

"We used to put just one linen cart on each unit, so nurses would take more than they needed to avoid an extra trip," Miller continued. "Now we put a cart on each end of the unit, so nurses can get more linen easily, but only if they need it."

They are also developing new ways to make beds that use less linen, and are discouraging nurses from using heavy blankets, which cost more to clean because they weigh more, to wipe up spills, for example. Staff members of departments such as X-ray and physical therapy, who used to automatically grab for linen to use indiscriminately, are being encouraged to use appropriate products.

Unfortunately, it isn't all so easy, Miller said. The Hospital has to replace $500,000 worth of linen each year, 80 percent of which is unaccountable. Operating room scrub clothes alone cost the Hospital nearly $94,000 each year. "We want to get everyone sensitized to the problem. We want all staff members to realize that when they take Hospital property it costs money," she stressed.

"There is not much more we can do but to try and control the problem by making the nursing service aware of the situation," added James Staight, director of patient transport services.

Aside from cutting linen usage, nurses are looking at other supplies that are being wasted. Switching to a larger size of absorbant pads, used to soak up discharge, for example, is enabling nurses to use fewer pads, Miller said. And rather than preparing products in advance that are not reusable, such as IV set-ups, she added, nurses are being encouraged to wait until the products are actually needed.

Physicians can help out in this area, Miller said, by reconsidering various procedures to determine if they're really necessary.

ADVISORY

Editors, news directors, assignment editors, reporters in the greater Bay Area:

We thought you might be interested in seeing the enclosed press code, which has been distributed to medical and administrative personnel at Stanford University Medical Center. It was revised and streamlined recently to comply with current legislation and is intended as a guide to what information may be disclosed about patients by hospital personnel.

Conversely, the guidelines indicate what information reporters might expect from the Medical Center. Despite our desire to comply quickly and efficiently with news media inquiries, we hope everyone understands that occasional delays will result as medical personnel deal with urgent medical needs. But the Medical Center's commitment under the Press Code will be met at the first feasible moment.

During business hours, the News Bureau will be happy to answer patient inquiries. After hours, a nursing supervisor is on call at (415) 497-6661 to help with routine inquiries. A member of the News Bureau staff is also on call through that same number if you need assistance.

If you have any questions about the Code, please feel free to call the News Bureau at any time.

Sincerely,

Mike Goodkind

(415) 497-6911

INSOMNIACS NEEDED FOR RESEARCH STUDY

STANFORD—

The Sleep Disorders Research Center at Stanford University Medical Center is seeking about 30 volunteers to test the daytime alertness of persons taking sleep medication.

Sue Cohen, a research assistant, said volunteers should be men or women aged 21 to 60 who are suffering from insomnia. They must be willing to take sleep medication during a 21-day period and spend 11 nights and six weekend days at the Sleep Center's lab in Palo Alto.

Three or four separate starting dates will be available through April, Cohen said.

Some volunteers will receive medication while others will get a placebo. Participants will be electronically monitored in the lab at night and perform skill tests during the day to test alertness.

Volunteers will be paid $400 and receive two free medical exams. Meals will be provided free during the live-in phase. Private rooms and amenities—including free movies—will be furnished.

For further information, contact Cohen at (415) 325-4697.

STATUS OF SCHOOL'S AFFIRMATIVE ACTION

STANFORD—

Despite inflation, cuts in funding, and an adverse climate for higher education, the School of Medicine has maintained its commitment to affirmative action, according to a faculty report recently made public.

Still, the Faculty Affirmative Action Committee added, there is much progress to be made in the area of minority recruitment at the Medical School, especially for minority faculty.

Minority representation in the various student categories as percents of the totals for 1981-82 was as follows (figures include Asian Americans, who, although not considered a disadvantaged minority by Stanford's internal criteria, must be included in statistics for federal reporting purposes):

- **M.D. degree candidates:** 34 percent;
- **Masters candidates:** 9 percent;
- **Ph.D. candidates:** 12 percent;
- **Housestaff (interns and residents):** 13 percent;
- **Postdoctoral fellows:** 7 percent.

Discounting Asian Americans, however, under nine percent of the total number of masters candidates, medical students, Ph.D. candidates, housestaff, and postdocs was comprised of minorities.

The percentages for women were:

- **Medical students:** 34 percent;
- **Masters candidates (mostly physical therapy students):** 81 percent;
- **Ph.D. candidates:** 31 percent;
- **Housestaff:** 27 percent;
- **Postdoctoral fellows:** 30 percent.

According to Dr. John Steward, associate dean for student affairs, "Women, like Asian Americans, are not considered a disadvantaged group, and there is no longer a special effort required to recruit them as students."

"All statistics on health, education, income, welfare, etc., identify the Black Americans, the Hispanic Americans, and the Native Americans as our currently disadvantaged citizens," states the report.

As documented, disadvantaged minorities were rarely found in the graduate programs or postdoctoral fellowships, where they could be prepared for academic posts.

-more-

"Changing this situation should be a top priority in affirmative action in the coming years," the report asserts.

"Faculty members traditionally come from a pool of postdoc M.D.'s and Ph.D.'s, so it's important to see who is 'in the pipeline' for future appointments at Stanford and elsewhere," explained committee chairwoman Alberta Siegel, professor of psychology.

The School made no progress in recruitment of minority faculty in 1981-82, as was true the previous year, the report found.

Women, however, comprised 23 percent of the 22 faculty members appointed, compared to 15 percent the previous year.

Still, the report indicates that for the past two years all faculty appointees at a rank higher than assistant professor were white males.

Siegel explained her committee's role in seeing to it that all faculty searches are widely advertised, and conducted along affirmative action guidelines.

Dr. John Wilson, associate dean for academic affairs, said, "As I sense it, the faculty and department chairmen are committed to affirmative action and the spirit of it as well."

The problem with disadvantaged minorities, he said, is "not that we don't look for them, but there really aren't large numbers of them to consider for the posts we have available."

He explained, "The standards for faculty appointment at Stanford are the same for all applicants. It's when you have two equally qualified candidates—which would happen very rarely—that you'd apply the principles of affirmative action in the selection process."

Steward said, however, that in considering disadvantaged minority students' applications to the M.D. program, the Admissions Committee may place a different emphasis on some of the information it is reviewing. "We tend in these cases to look more at the 'distance traveled'—the promise and potential of an individual—as opposed to tangible achievements."

This fall's entering class, he said, enrolled 65 percent of the minorities who had been accepted to the School; the figure for non-minorities was 53 percent. "I think this had to do perhaps with the fact that we made a large effort to recruit minorities," he said, adding that there are "few medical schools in the U.S. that do better than we do in meeting financial aid needs."

Still, "One major reason we lose many medical students who would otherwise come here is the cost of coming to Stanford, considering tuition and other living expenses," said Diane Winkle, director of the Office of Student Affairs.

The Medical School tuition for the 1981-82 year was $8,340. Currently it's $9,591, and the estimated tuition for the 1983-84 year is $10,932.

-more-

More than 80 percent of Stanford's medical students receive at least some financial assistance. Proposed federal legislation may result in a 50 percent decrease in available low-interest funding for student loans, according to the School's financial aid administrators' predictions.

Students and administrators fear that the number of applicants to medical school—at Stanford and elsewhere—will decrease. Those who do apply will most likely be from a more homogeneous segment of society.

Steward noted that the current year's minority representation in the School's student body has dropped by one or two percentage points since 1981-82. "This is a national phenomenon right now, which we're hoping is not a trend," he said.

"Stanford traditionally has done very well in recruiting disadvantaged minority M.D. candidates. National figures for the 1980-81 year indicated that of the 117 medical schools in the U.S. (excluding three with predominantly minority student bodies), Stanford had the third highest percentage of minority students." Only three of the 117 schools had greater than 20 percent disadvantaged minority enrollment, Steward said, and Stanford was one of these.

He added, "Our financial aid programs are adequate for awhile, but we aren't sure what will happen after the next couple of years. But with the School's goal of producing academicians and researchers, who are among the lowest paid in medicine, we must provide aid to encourage students to pursue these areas."

The hiring of an assistant dean for student affairs to attract outstanding minority students headed for academic careers was recommended by the School's faculty senate last spring. While no formal search is yet under way, a committee headed by Dr. Roy Maffly, director of Admissions, is defining criteria for such a post.

For the 1981-82 year, the members of the Faculty Affirmative Action Committee were the following members of the School's tenured faculty: Margaret Billingham, M.B., associate professor of pathology; Byron Brown, Jr., Ph.D., professor of biostatistics; Gary Gray, M.D., professor of medicine; Michael Marmor, M.D., associate professor of surgery; Eric Shooter, Ph.D., professor and chairman of neurobiology; and Dr. Siegel.

WOMEN SUBJECTS NEEDED FOR STUDY

STANFORD—

Female volunteers aged 40-80 are being sought by the division of clinical pharmacology to participate in an ongoing drug study at Stanford. Needed are healthy, Caucasian, non-smoking females, who are currently taking birth control pills or estrogen.

Entitled "Comparative Drug Metabolism: Effects of Aging in Man," the study examines age-related changes in liver clearance of drugs metabolized by different pathways. Principal investigator is Dr. Terrence Blaschke, chief of the division and associate professor of medicine and pharmacology.

The study began in January, 1981, and plans are to recruit 13 more subjects within the next four to six months.

Subjects will spend one week in the clinical research center at Stanford. Three relatively non-toxic drugs will be administered to the volunteers. (Side effects, if any, are minimal, according to research nurse Marni Brown.) Blood samples will be taken, with the purpose of observing how the different drugs are broken down in the liver.

Subjects are currently sought for the weeks of Jan. 17 and 24. Participants will receive compensation.

For further information, call Brown at 497-5266.

FIGHTING GONORRHEA: GENETIC ENGINEERING PROVIDES CLUES

STANFORD—

Stanford microbiologists are using genetic engineering techniques in an attempt to "pull the teeth" of the organism that triggers gonorrhea.

By manipulating the genes of gonococcus bacteria, the scientists have, for the first time, found a way to test an enzyme long suspected to be a weapon the bacteria use to produce the malady.

"If the enzyme turns out to be as important as we think it may be, it could be useful in constructing new ways to provide protection against gonorrhea," said Stanley Falkow, chairman of Stanford's department of medical microbiology.

Knowledge about the enzyme may lead to a vaccine or similar combatant against gonorrhea, Falkow said.

A major obstacle to creating a useful gonorrhea vaccine has been the gonococcus bacterium's ability to disguise itself, said Falkow.

Most bacteria wear a membrane coat that is studded with protein tags. Cells in the human immune system use these tags to identify the foreign bacteria, which they then destroy.

But the gonococcus can mutate and subtly change the configuration of its proteins, effectively camouflaging itself against the body's defenses.

"What you would like to do with an organism that can change its face like that is pull its teeth so that it can't cause an infection," Falkow said. "In other words, it could still multiply in the body, but not cause tissue damage."

The "tooth" in the case of gonorrhea may be an enzyme, called "IgA1 protease," that Falkow and a graduate student, J. Michael Koomey, have studied.

The bacterium uses the enzyme as a chemical cleaver that snips in two the normal antibodies a healthy person makes to fight off infection.

In response to an increasing number of invading bacteria, the human body produces more antibody. In turn, the bacteria produce more enzyme to destroy the antibody. The infected person loses the battle as he develops the genital sores and sometimes serious complications associated with gonorrhea.

-more-

Koomey and Falkow have identified the gene that is responsible for "telling" the bacteria how and when to produce the enzyme. Through a series of steps, described in the December *Proceedings of the National Academy of Sciences*, the scientists have been able to eliminate that single gene from the bacteria, creating an organism that is like gonococcus in every way, except that it can't make the critical enzyme.

The "impotent" organism now serves as a research tool in understanding the role of the enzyme in causing disease.

Normally, the next step in research would be to compare the responses of laboratory animals injected with either gonococcus or the engineered bacteria. But the crucial enzyme destroys only one specific human antibody, which is not present in animals.

This specificity makes the usual testing of the virulence of the bacteria in rodents and primates impractical, Falkow said, and has slowed research.

"If we can prove that the enzyme plays a role in disease, there are research groups interested in carrying the work a step further, to determine whether or not the engineered bacteria could be useful in providing protection against disease," Falkow said.

Although penicillin and its derivatives can effectively stop most acute bouts of gonorrhea, the antibiotics are only a temporary solution to the sexually transmitted disease, he added. Already, virulent strains of the bacteria have evolved that are resistant to penicillin.

"Another important reason we're interested in this particular enzyme is that it is also found in several organisms that cause meningitis (a dangerous infection of the membranes that surround the brain and spinal chord)." In contrast to gonorrhea, meningitis is not easily treated with antibiotics and is often fatal.

"The three major forms of bacterial meningitis all probably have this enzymatic strategy," Falkow said. "So we aren't just addressing the problem of gonorrhea, but also the more general question of the strategies bacteria use to cause disease.

"From the 1940s through the '60s, it was usually felt that through the use of antibiotics, infectious diseases caused by bacteria would be conquered, that we'd simply be able to treat them," Falkow said. "But through the advent of resistance, it became apparent that this was not going to be possible in many cases.

"There's another fundamental flaw in antibiotics," he added. "You have to wait for someone to get ill, and the whole basis of medicine really should be preventative."

NEW COMPREHENSIVE CARE CLINIC FOR DIABETICS

STANFORD—

A new clinic to specifically address the health care needs of the diabetic patient will open Thursday, Jan. 6, at Stanford University Medical Center.

An idea that's been considered for some time in the Division of Endocrinology, the Diabetes and Metabolism Clinic is finally coming to fruition for a variety of reasons, according to Dr. Fredric Kraemer, the endocrinologist slated to head it.

"Until now we've treated diabetic patients in the Endocrinology Clinic, but we were unable to deliver as comprehensive care as we'd like to." This, he said, was because of complications associated with the disease, and because of the necessary patient education involved.

"But besides directly helping patients, the new clinic will help investigators to gather more of our own data by concentrating all diabetic patients within a single unit where their problems can be studied by the variety of specialists who have interests in them."

Until now, he said, "We would refer diabetic patients with neurological complications to the Neurology Clinic, renal complications to the Renal Clinic, and so forth. With the new clinic, we plan to include experts from a variety of specialties on the regular staff.

"We hope that communication among the various physicians will be improved," he added.

Some of the specialists participating in the clinic will be podiatrists, nutritionists, nephrologists, neurologists, and ophthalmologists. Drs. Gerald Reaven, professor of medicine and chief of the Gerontology Division, and Michael Greenfield, clinical assistant professor of medicine, will be the two other staff endocrinologists.

"Most of the major complications associated with diabetes," explained Kraemer, "affect a patient's renal function, peripheral nervous systems, or eyes. There can be peripheral vascular disease too, showing up symptomatically first as infections or sores on the feet, and sometimes leading to amputation."

-more-

But if physicians can identify these problems early in treatment of the diabetic, he said, "we can try to prevent their progression, although success with this type of intervention remains to be proven for all of the symptoms."

Thus the major impact of the new clinic, as Kraemer sees it, will be in the aggressive metabolic control of glucose levels in hard-to-manage diabetic patients.

"Although we'll be seeing all diabetic patients, the uncomplicated ones will return to their primary physicians for follow-up care," he said.

The Diabetes and Metabolism Clinic is being set up as part of the Endocrinology Clinic. "Our division has recently been expanding," Kraemer explained, "and with the addition of new faculty we have increased clinical capabilities which allow us to undertake a project like this.

"It was decided that when new faculty members with interests in metabolism were added, we'd head the Endocrinology Clinic in this direction," said the newly appointed assistant professor of medicine, who for the past four and a half years has worked as a postdoctoral fellow at Stanford.

The new clinic will improve comprehensive care for diabetic patients, Kraemer predicts, since the care will be delivered in a focused, "rather than in a scattered fashion."

He is hoping, for example, to effectively involve the nursing staff in educational efforts, such as the teaching of home glucose monitoring.

The clinic will see adult patients with both insulin-dependent and non-insulin-dependent diabetes, said Kraemer. The former type, he explained, usually but not always begins in childhood, while the latter type is often "adult-onset."

"Insulin-dependent diabetics absolutely must have insulin for their entire lives," he said. "Non-insulin-dependent diabetics have increased blood glucose, and while they're sometimes treated with insulin, they can also often be treated with oral agents or diet."

The reasons for the two types of diabetes are different and their management is often different, Kraemer said, but they can lead to the same kinds of complications.

The clinic will also treat non-diabetic patients who have lipid abnormalities, such as elevations in cholesterol or tryglycerides, Kraemer said.

It is to be located at the Medical Specialties Clinic on the first floor of the Boswell Building. To make appointments, patients or referring physicians should call Ingrid Gallo, at (415) 497-5947.

LOW CALORIE DIETS AND HEART ATTACKS: A WARNING

STANFORD—

Persons on diets of 800 kcals or less per day may be endangering their health even if under a doctor's supervision, say both a physician and a dietician at Stanford University Medical Center.

"It is certainly sound advice for persons to work with their physician when starting a diet. But extremely low calorie diets may cause a breakdown in structural protein, including heart tissue," said Peter Rudd, assistant professor of medicine.

"With a breakdown in heart tissue comes a risk of cardiac problems. These can occur suddenly and without warning. Even if a patient is hospitalized and constantly monitored, heart problems may still occur. Some are easily corrected, but others could be fatal," said Rudd, an internal medicine specialist.

Rudd and Stanford University Hospital (SUH) registered dietitian Jane Woeckener were interviewed separately in the wake of public interest triggered by the death of a Bay Area woman who reputedly adhered to a low calorie diet and by articles offering reassurances about various diet plans.

"There are no easy answers when it comes to dieting," said Woeckener, who serves as assistant director of dietetics at SUH. "But the safe and sensible way to lose weight involves eating a wide variety of low calorie foods from the basic four food groups (dairy, meat, fruits/vegetables, breads/cereals) and planning a slow, steady weight loss of about two pounds per week.

"Diets below 1,200 kcals for women and 1,500 kcals for men are generally not recommended because they almost always are lacking in important nutrients needed to meet minimum Recommended Dietary Allowances (RDAs) and to maintain health. (Kcal is short for kilocalorie and is the commonly accepted measurement of the energy value of food.)

"Behavior modification and changing the attitudes and habits which lead to being overweight in the first place are crucial components of weight loss. Crash diets with temporary results do not significantly lower the risks associated with obesity," Woeckener added.

Both Woeckener and Rudd cited recent studies suggesting that diets of fewer than 800 kcals per day are potentially dangerous. These studies, Rudd noted, examined several different nutritional regimens. The number of calories and variety of components appeared to be more important than the specific content of the diet, he said.

-more-

Woeckener and Rudd said that an extremely low calorie diet may be desirable only when someone is so obese that the risk of sudden death is high unless weight loss begins quickly.

"In these circumstances, the patient frequently is already hospitalized. Close observation will not eliminate the risk of sudden death while rapidly losing weight but would at least permit health professionals to respond quickly to a cardiac arrest," Rudd said.

He added that the heart is especially vulnerable to damage on a low calorie diet, even if protein is its main component. The addition of modest amounts of carbohydrates may reduce breakdown of the body's structural protein and may help protect the heart.

"But there have been reports of lowered potassium, calcium and magnesium, which could make irregular heart rhythm more likely. These electrolytes (blood minerals) are necessary, and they are best provided within the context of a well balanced diet," he added.

Among the studies cited by Rudd and Woeckener was one published in the April 1981 edition of *The American Journal of Clinical Nutrition.* Authors included Harold E. Sours, M.D., formerly of the Bureau of Epidemiology of the Center for Disease Control in Atlanta, and Victor P. Frattali, deputy director of the division of nutrition of the Food and Drug Administration, which currently is examining low calorie diets.

The article studied 17 individuals who died of heart attacks suddenly after long periods on very low calorie diets, consisting entirely or primarily of protein.

"The deaths appeared to be independent of type of medical supervision received during the diet, daily dosage of potassium supplementation and biological quality of the protein product used," the authors said. The 17 individuals had been on diets of about 300 to 400 kcals per day.

"We conclude," the article stated, "that use of very low calorie weight reduction regimens should be curtailed until further studies determine what modifications if any can insure their safety."

Contacted in Washington, Frattali said the article represented the research of himself and colleagues and did not indicate an official agency endorsement or warning. Officially "we're trying to keep ourselves informed in regard to low calorie diets," he said.

On Dec. 30, the FDA issued a public statement that diets under 400 kcals per day "are physiologically unsound regardless of their overall nutrient composition.

"FDA believes their use should be considered experimental and patients should have full knowledge of the risks, and undertake the diet only with proper medical supervision."

Diets under 800 kcals per day should be used only under proper medical supervision, the FDA said.

(Editors: The Medical Center News Bureau has available for the news media a packet of recent articles, including the Sours/Frattali piece, which will be mailed on request.

RECIPE BOOK BENEFITS NURSING GROUP

STANFORD—

Ever tasted Kay Zehr's persimmon pudding? Jeanne Kennedy's semi-truffled pate? Or Caroline Zlotnick's Mexican fiesta salad?

If these recipes sound especially tempting, they can be found in the newly-published *Favorite Recipes of the Friends of Nursing.* The cookbook is now for sale, for $10, in the Nursing Administration Office, the Hospital gift shop, and at both Stanford bookstores (on campus and at 135 University Ave., Palo Alto).

Favorite Recipes was compiled by Jane Binger, R.N., Ed.D., and Patricia Allen Sparacino, R.N., M.S., and features family-tested recipes from around the world. Contributors include more than 300 nurses in clinical, educational, and management roles at Stanford University Hospital, Clinics, and Cowell Student Health Center, and nurse alumnae of Stanford University.

Recipes range from simple, easy-to-prepare delights like mud pie and chicken-on-Sunday, to more sophisticated specialties such as almond pear supreme and eggplant parmigiana.

Binger is a relief staff nurse in orthopedics at Stanford and a lecturer in the master's program in community health administration, department of nursing, San Jose State University. Sparacino is a clinical nursing specialist in cardiovascular surgery, University of California, San Francisco. Both are charter members of Friends of Nursing and alumnae of Stanford University.

The book may be purchased at any of the locations listed above, or may be ordered by mail for $12 by sending name, address, and check or money order to Friends of Nursing, Nursing Administration, C020, Stanford University Hospital, Stanford, CA 94305.

All proceeds from the sale of the cookbook will go to Friends of Nursing, a newly-founded philanthropic organization dedicated to fostering excellence in nursing at Stanford. For information about joining the group, call (415) 497-5311.

PUBLIC INVITED TO HEAR GUEST SPEAKER ON MULTIPLE SCLEROSIS

STANFORD—

Dr. Byron Waksman, a noted investigator in neuroimmunology, will deliver the seventh annual George A. Zimmermann Lecture at Stanford University Medical School Friday, March 4.

His talk, "Is Research on Mutliple Sclerosis Getting Anywhere?" will begin at 4 p.m. in the Fairchild Auditorium. It is open to the public.

Waksman, an internationally recognized authority on immunology, has been director of research programs, National Multiple Sclerosis Society, since 1979. He has made numerous contributions to the understanding of immune disorders of the nervous system.

Waksman was appointed professor of microbiology at the Yale University School of Medicine in 1963, and in 1964 he became chairman of the department. Since 1979 Waksman has been an adjunct professor of pathology and biology at Yale University and adjunct professor of pathology at New York University. He served as president of the American Association of Immunologists in 1970-71.

Waksman has published more than 250 papers in the field of immunopathology, especially dealing with autoimmune reactions, reactions of "cellular" hypersensitivity, the role of the thymus, specific acquired tolerance, suppressor cells and their mediators, cyclic nucleotides in the regulation of immune responses, and cell cycle phenomena in lymphocyte function.

The Zimmermann Lectureship was established by the Department of Neurology in 1977, as part of a gift by the late George A. Zimmermann, a long-time San Francisco businessman, for multiple sclerosis research and treatment at Stanford.

Previous speakers have included Barry Arnason (1977), Richard Johnson (1978), Guy McKhann (1979), John Kurtzke (1980), Ian McDonald (1981), and Kenneth Johnson (1982).

STANFORD—

A contract with the state to continue to provide care for Medi-Cal patients has been signed by Stanford University Hospital officials.

Stanford was among six hospitals on the Peninsula notified by telephone Feb. 4 by the Medi-Cal special negotiator that a contract would be sent for hospital review and signature. The contract, effective March 1, was negotiated under a law passed last year by the state Legislature in an effort to reduce Medi-Cal costs.

The effect on most hospital operations at Stanford will be minimal. In fact, "physicians, patients, and most of our staff will not notice any difference when the contract takes effect," said Sheldon S. King, executive vice president and director. "The same authorizations for treatment will be required, and there will be no change in the care patients receive."

The main change will be in the billing department, he said. The hospital will be reimbursed at a single daily rate for each patient, regardless of the severity of the illness or the extent of the treatment.

In the past, the state reimbursed hospitals for "reasonable" costs incurred for treatment of Medi-Cal patients. These costs differed according to the intensity of care and amount of services required by the individual's illness.

King said that if the current level of Medi-Cal patients at Stanford is sustained, the hospital will be able to manage with the current single reimbursement rate. If, however, it receives a heavy load of very ill patients requiring intensive and expensive care, the new rate might be difficult to accept for a prolonged period.

"I expect that the mix of cases of patients requiring major and minor levels of care will enable us to sustain the one-rate arrangement for the immediate future," he said.

The reimbursement rate will be renegotiated annually, and both the state and the hospital have the right to cancel the contract with 120 days' notice.

Specific conditions of the Medi-Cal contracts are not made public. Hospitals negotiated for contracts without knowledge of other hospitals' rate proposals.

The Medi-Cal changes are derived from the first of two new laws passed by the Legislature last year bringing fundamental changes in the way health care is paid for in the state. The second law allows private insurance companies to negotiate prices in advance for their subscribers with specific hospitals and doctors.

Insurance companies can write reduced rate packages for groups of patients receiving care from these providers, although patients might be required to pay more for coverage of high-priced services.

According to King, Stanford Hospital officials are in preliminary discussions with several insurance companies.

FOR IMMEDIATE RELEASE

STANFORD GAYS PLAN NEW SCHOLARSHIP OFFER

STANFORD—

The Gay and Lesbian Alliance at Stanford (GLAS) plans to offer the University scholarship funds for a medical student who has shown a commitment to serving the gay community.

The funds would not be limited by sex or by the sexual orientation of the recipient.

The GLAS Steering Committee already has raised $550 toward such a scholarship and will seek additional funds for this purpose before April 15.

Meeting with University attorneys Russ Meyer and Iris Brest, GLAS representatives expressed hope the new scholarship would meet objections raised by the University to an anonymous gift offer of $500 toward a scholarship restricted to males who publicly identified themselves as gay.

Douglas Bernard of GLAS said the group would contact the anonymous donor, who had asked the University to inform the Gay People's Union at Stanford, the predecessor of GLAS, about the initial offer. GLAS hopes to enlist the prospective donor's support for their new proposal.

"Should the University refuse this (new) scholarship offer, the GLAS Steering Committee will attempt to negotiate modifications to the gift restrictions which are acceptable to the University and consistent with the spirit of the offer," according to a GLAS news release.

"GLAS believes it is important that the gay community demonstrate its willingness to work with the University administration, and that the University demonstrate its willingness to work with the gay community. . . .

"We hope the proposed scholarship will not only assist a medical student with a commitment to gay health care, but that the very existence of the scholarship, and its administration by a major university, will help make gay health care a more accepted and legitimate field of practice within the medical profession. . . .

"Besides the shortage of health care professionals with skills and commitment to serve the gay community. . .there has been little research directed at the health care needs of gay people."

Among the ways a commitment to serving the gay community might be shown, GLAS said, are 1) active involvement in an organization oriented toward serving the gay community, 2) pursuing a course of studies directed service to the gay community, or 3) doing research specifically directed toward developing health care techniques for gay men and lesbians.

Meyer noted that fairly wide consultation within the University would be needed before a decision would be reached on the prospective offer.

GLAS said that if an agreement could not be reached which was satisfactory to the Steering Committee, all funds collected would be returned to the original donors.

TAINTED HEROIN PROMPTS NEW UNDERSTANDING OF PARKINSON'S DISEASE

STANFORD—

The freak accident in a drug dealer's laboratory that sent several young Bay Area heroin users to the hospital with symptoms of Parkinson's disease last summer may have opened a new door to understanding and treatment of the disease, according to research by Stanford University scientists.

A poison, probably made as an accidental byproduct when a kitchen chemist used too much heat or acid in preparing a homemade batch of a narcotic, has been found to selectively kill cells in the part of the brain most severely affected by Parkinson's. If the drug induces the same symptoms in laboratory animals— and preliminary research indicates that it does—the physicians may have uncovered an animal model for the disease.

"The six young people we have studied have symptoms that are virtually indistinguishable from Parkinson's," said J. William Langston, an assistant professor of neurology at Stanford who conducts clinical research at Santa Clara Valley Medical Center in San Jose.

"The rigidness of posture, slow movement, and tremors are classical Parkinson's symptoms. But Parkinson's is a disease of the elderly, and these are young people. We were stunned when they came in."

Langston and colleagues Philip Ballard, James Tetrud and Ian Irwin report their findings in the Feb. 25 issue of*Science* magazine.

The findings are significant for two reasons, Langston said. "First, if the drug has the same action in animals—and early indications from the National Institute of Mental Health indicates that it does—we'll have a new way of studying potential treatments for Parkinson's disease."

Scientists could use the drug to create a model of Parkinson's disease in rodents, he said. Until now, that goal has been blocked because no other substance tested is specific enough to selectively affect only those cells responsible for Parkinson's.

"The second implication is more theoretical, but potentially just as important," he said.

"No one knows why, but in some diseases, such as Parkinson's, only certain specific brain cells die. One theory says that as some people get older, waste products accumulate in these nerve cells—the cells can't take out the garbage.

"Now we have a drug that we're pretty sure is toxic to only these cells," he said. "As we learn more about the chemistry and function of this drug, we may get a clue to understanding what's happening in the natural disease."

The chemical culprit responsible for the artificial Parkinson's seems to be 1-methyl-4-phenyl-1,2,5,6-tetrahydropyridine, called MPTP for short. Used as a tool in synthesizing other chemicals, MPTP has had no known biological properties, and has been readily available from the Aldrich Chemical Company for years, Langston said. However, he added, the recent findings have prompted the Bureau of Narcotics to begin reclassifying the chemical as a "controlled substance."

2-23-83

-more-

Langston theorizes that, while attempting to make a drug similar to the analgesic Demerol with "a little more kick," a drug dealing chemist mistakenly produced MPTP instead, and sold it on the street as heroin. Drug users from Salinas to Santa Clara county bought the contaminated drug, and at least six developed full blown, advanced stage Parkinson's symptoms.

While researching the bizarre occurrence of the disease in young people, Langston and his colleagues found a case reported in 1979 of a graduate student who developed the same symptoms after injecting homemade drugs.

"For four to six months he had been synthesizing MPPP (using a reaction which produces MPTP as a by-product) and injecting it intravenously without problems," the researchers write. (MPPP stands for 1-methyl-4-phenyl-4-propionoxy-piperidine, a chemical closely related to MPTP in structure). Apparently, after taking several "shortcuts" in synthesis and injecting the resulting product, he developed marked parkinsonism."

When the student died of a drug overdose two years later, an autopsy of his brain showed substantial, selective damage to his substantia nigra, an area half the width of a pencil and two inches long at the base of the brain, that is involved in coordinating movement. Damaged cells from that region looked "indistinguishable" from analagous cells in elderly patients with advanced Parkinson's disease, Langston said.

"This situation is both tragic and ironic," Langston said. "Usually scientists try a lot of substances in animals first, in their attempts to understand mechanisms and treatments of disease, long before they're tested in humans. It's very ironic to develop the animal model in humans first."

All six of the patients Langston has thus far studied injected multiple doses of the drug, ranging from five grams over four days to 20 grams over five to eight days.

"But we have some evidence that even one dose of this chemical may have permanent effects," said Langston, who urged anyone who thinks they may have used some of the contaminated drug to contact the Department of Neurology at the Santa Clara Valley Medical Center [(408) 279-2546] for confidential testing. "Heroin" contaminated with MPTP triggers a burning sensation during injection, and frequently causes hallucinations, said Langston. Precise laboratory tests can confirm or debunk a suspected case of MPTP poisoning.

"Though the people who have had only one or two doses may have no Parkinson's symptoms now, they may be at greater risk for developing symptoms at some point in the future," Langston said.

Though the exact mechanism of Parkinson's disease is unclear, one result of destruction of the brain cells is a reduction in the vital neurotransmitter dopamine. In current treatment for the disease, Parkinson's patients take daily oral doses of "L-dopa," a substance the brain can use to make more dopamine. Patients with the disease get progressively worse over a number of years, though the L-dopa treatments can permit them to return to normal lifestyles.

The patients Langston has studied who injected MPTP have responded just as well to L-dopa treatments, he said. However, side effects from L-dopa, such as movement disorders, which usually occur in Parkinson's patients only after years of treatment, already are appearing in some of the young patients.

LIFE AND DEATH DECISIONS GETTING TOUGHER FOR DOCTORS, SAYS M.D.

STANFORD—

One night a depressed college sophomore raised a shotgun to her own neck and pulled the trigger. Instead of killing her, the blast destroyed her spinal column and crushed the bony vertabrae of her neck.

The extent of brain damage was unclear, but physicians were certain that her limbs were completely paralyzed and that she would never speak again. Artificial breathing machines, drugs to boost the pumping of her heart, and an artificial kidney machine were necessary to keep the young woman alive. Family members were adamant that the machines be turned off. The physicians were faced with a decision.

"The family said 'Take my daughter off life support.' What would you do?" Tom Raffin asked the 300 laypersons gathered at Stanford University Wednesday to hear him discuss the practical and moral issues faced each day in a hospital's intensive care unit.

"Turn the machines off," said several members of the audience, but Raffin, assistant professor and assistant chief of medicine and associate director of Stanford's 60 bed intensive care unit, cautioned them not to be hasty.

"She tried to commit suicide, that's true, but that's no reason to let her die," Raffin said. "If you are a physician, who are you responsible to, the family or the patient? Several hundred thousand patients a year try to commit suicide. The great majority of these take drug overdoses and must be placed on respirators. Many of these recover and then go on to live productive lives."

"You might say, 'but what about the idea that she faces such a miserable life?' Well, what about the soldiers in Vietnam who were shot in the neck and were forced to go on breathing machines? You can visit them at VA hospitals around the country....You can see how complicated this is," Raffin said. "These are not easy situations to deal with, but decisions have to be made."

The decisions may become tougher, Raffin said, as medical costs skyrocket. Currently, there are more than enough ICU beds in the 6,000 U.S. hospitals to care for all critically ill patients, at an average cost of $2,000 each day. But the number of beds available may soon drop.

"With the recent changes in health care legislation and the coming changes in benefits from private insurance, there will be a limit to the number of intensive care unit beds in the future," Raffin said.

-more-

2-17-83

"The old days of triage decisions are going to come back," he predicted. ("Triage" refers to a method of prioritizing patients for treatment in a way that maximizes the number of survivors).

"When you have a seventy-year-old and a thirty-year-old who are equally critically ill and you have one bed, the thirty-year-old gets the bed," Raffin said. "The seventy-year-old who might be salvageable doesn't get the bed and has a greater chance to die. Those days will be coming back, and I believe the people who will first experience the brunt of those tough decisions are the underprivileged."

Eventually though, nearly everyone will be touched by the painful choices of the intensive care unit, either personally or through a family member or friend, said the physician. With even the best health insurance paying only 80 percent of an ICU bill, several weeks or months in an intensive care unit can render even financially stable families monetarily, as well as emotionally, bankrupt.

The high costs stem from expensive life support and monitoring equipment such as respirators, artificial kidney machines and heart and lung monitors that the critically ill patient needs to stay alive, as well as from the host of physicians, nurses and specialists who render round-the-clock health care.

If the patient can be healed and returned to a reasonable quality of life, the cost is well worth it, Raffin said. The tragedy comes for the significant percentage of all ICU patients who have essentially no quality of life and are suffering for weeks in ICUs on extraordinary life support systems.

"Cost is not the most important issue," Raffin said, "though it is important." More important is the reality that many ICU patients languish for weeks or months in a critically ill state with almost no chance to recover, while anguished families and health care teams try to guess what choices the patient would make if he could talk.

A "living will," which frees the family and physician to withdraw extraordinary means of life support once it has been determined that the patient has almost no chance of regaining "an acceptable quality of life," is an important document that everyone should sign, Raffin said.

Though "acceptable quality of life" could be different for each individual, the working definition in Stanford's four ICUs is the ability to leave the hospital, he said.

While such a will would not prevent, for example, an elderly patient from being put on a breathing machine in the emergency room, it could be used to help the family and health care team decide whether or not to withdraw artificial life support when a comatose patient is deteriorating after several weeks on a breathing machine.

Such wills can be obtained in the chaplain's office of most hospitals, said Raffin.

"I believe it's very important for people, young or old, to discuss with their family, friends, and physicians their ideas and viewpoints about being on life support equipment in an intensive care unit," Raffin said. "If there is 'almost no chance' for survival, do you want your family and friends to work with physicians in withdrawing you from external support?"

Raffin's was the first in a series of six weekly lectures at Stanford on the progress and ethical dilemmas of intensive care. Admission is free for all the "Progress in Medicine" lectures, which will begin at 7:30 pm on successive Wednesdays in the medical school's Sherman Fairchild Auditorium. Further information can be obtained by calling the Medical Center's office of public events at (415) 497-6389.

SUH CHIEF OF STAFF DECRIES PROPOSED REGISTRATION OF "HEALERS" AS HEALTH CARE PROVIDERS

STANFORD—

A proposed change in California's Medical Practice Act would ultimately decrease the quality of health care if passed, said Dr. James Silverman, chief of staff at Stanford University Hospital.

Silverman reviewed the reasons for, and the effects of the suggested revision that would allow a group of nonphysician practitioners to register with the state as health care providers, in the recent issue of *Stanford M.D.* The magazine is published by the Stanford Medical Alumni Association.

"The proposal would accept unorthodox and unproven therapies as having real value and classify them as health care services," said Silverman. "It would legalize quackery, and mock the present stringent controls of new drugs and new therapies."

Sponsored by the Board of Medical Quality Assurance (BMQA), the proposal calls for rewriting Section 2052 of the Medical Practice Act to allow alternative practitioners such as homeopaths, lay midwives, naturopaths, Indian shamans, and body workers to register with the state in order to treat patients. "They would be required to simply inform their clients of their training and background," Silverman explained.

The BMQA is California's regulatory agency charged with overseeing medical quality assurance, licensing, and allied health professions. It is made up of 12 physicians and seven nonphysicians.

The Medical Practice Act now states only physicians may diagnose and treat any mental or physical disorder. The change would register nonphysician practitioners, which would allow them to treat patients. "Even if they are only registering with the state, it still implies their acceptance as health care providers," Silverman commented.

2/16/83

-more-

"Nonphysician practitioners do fulfill a perceived need of society. The question is whether their services fall under health care, are good for sick people, and whether they should be available to replace scientifically proven treatments," Silverman said. By condoning registration of this group of practitioners, he added, "the public may be mislead into thinking they are qualified to substitute for trained people (physicians) in caring for the sick."

The proposal has been a controversial issue since its inception, and legislative action on it has been delayed a number of times. Public hearings were held in January 1983 in San Francisco, and are scheduled for Feb. 19 in Los Angeles.

The controversy over the proposal has been presented as a battle between organized medicine and the "healers," Silverman said. Proponents feel some illnesses need not be treated by physicians, but rather nonphysicians can provide cheaper, faster care. They also feel alternative providers are necessary to make health care affordable by all segments of society.

Opponents feel physicians, because of their vast amounts of training and experience, are the only ones with the skills and confidence necessary to make diagnostic decisions.

"The belief that it is possible to have effective, less expensive, and successful health care services rendered by nonphysician practitioners seems to be based on the assumption that cheaper—albeit inferior—care is better than no care at all," Silverman said. "This assumes that nonphysicians know enough about medicine to do at least some good.

"Unfortunately," he concluded, "much alternative providers' knowledge is based on folklore, stylish fads, and other non-scientific sources. They have little, if any, knowledge of the human body or medicine."

LIFE IN THE COSMOS COURSE FOR M.D.s

Science writers: On Saturday and Sunday, Feb. 26 and 27, Stanford University School of Medicine will offer a minicourse "Life in the Universe" for physicians attending a week-long continuing education program, "Basic Science for Clinicians." Even though "Life in the Universe" is a course for which there is tuition, members of the press are invited free of charge. The sessions will be in Fairchild Auditorium. Program copies available on request if not included with story—Andreopoulos.

STANFORD—

Physicians and biomedical scientists who attend Stanford University's annual course "Basic Science for Clinicians" will be in for a special treat Feb. 26 and 27 in Fairchild Auditorium.

After a week-long review of medical science on earth, the doctors will be exposed to a minicourse on "Life in the Universe," particularly the controversial search for extraterrestrial intelligence now sponsored by the National Aeronautics and Space Administration (NASA).

The special course has been organized by Dr. Edward Rubenstein, associate dean for postgraduate medical education, and Dr. John Billingham, chief of the Extraterrestrial Research Division at NASA's Ames Research Center in Mountain View, Calif. It is open to physicians and non-physicians, and tuition is charged.

Why should a course about life in the cosmos interest a group of medical specialists?

By any yardstick earth is but a minor planet of a below-average star in the galactic boondocks, goes the reasoning. As far as science goes, life is simply the end result of a batch of chemicals excited by a star's energy and mixed in a certain way. If life can exist on earth, it can occur elsewhere.

"A course for clinicians shouldn't necessarily restrict the discussion of recent scientific advances to those issues directly connected with medical science," said Rubenstein. "Physicians have strong interest in areas of research beyond medicine, especially when they have deep biological relevance."

The program Feb. 26 will begin at 9 a.m. and will cover these topics: "The Biogenic Elements of Compounds: From Stardust to Planets," " The Search for Other Planetary Systems," "Chemical Evolution and the Origin of Life," and "The Origin and Evolution of Molecular Asymmetry."

Speakers from NASA-Ames Research Center will include Billingham; Sherwood Chang, chief of Extraterrestrial Research Division; and James G. Lawless of the Chemical Evolution Laboratory. The Stanford speaker will be William A. Bonner, professor of chemistry. (*Editor's note: Prof. Ronald N. Bracewell of Stanford's department of electrical engineering and author of* The Galactic Club: Intelligent Life in Outer Space, *originally listed on the program, will not appear because of illness.)*

The program Feb. 27 will deal with "Precambrian Biology," "The Evolution of Complex Life," and "The Search for Extraterrestrial Intelligence."

2/16/83 -more-

2-2-2 Speakers include Harold P. Klein, director of Life Sciences at NASA-Ames Research Center; Kevin Padian, assistant professor of paleontology at the University of California, Berkeley; and Bernard M. Oliver, retired vice president for research and development at Hewlett-Packard Corporation, Palo Alto.

Stanford is an especially appropriate locale for the course, Billingham said, "because of the many faculty links here."

It was Nobel Laureate Joshua Lederberg, now president of Rockefeller University, who back in the fifties coined the word *exobiology*, the search for extraterrestrial living organisms.

Lederberg's colleagues designed devices that would study chemical events on other planets, including possible life forms. They served as principal researchers on the Viking 1975 lander imaging team and the 1971 Mariner Mars mission. Some of the instruments they designed are now used in the fields of biology and medicine.

Prof Allen M. Peterson of Electrical Engineering at Stanford is currently involved with NASA's Search for Extraterrestrial Intelligence program (SETI), according to Billingham.

Peterson, he said, is building a special machine called a Multichannel Spectrum Analyzer to aid in the detection of radio signals that might be transmitted by other civilizations out in the galaxy.

"We don't know what frequencies to look for," Billingham said, "but we do know there's a region of the spectrum that's best to start in, called the Microwave Window."

This is a huge region with 10 billion channels, according to Billingham. There is no machine that can listen to so many separate channels all at once. To reduce the odds, a prototype 74,000 channel analyzer is being built in Peterson's laboratory. Using a sophisticated data processing system, the machine will aid SETI scientists in distinguishing radio signals which occur naturally in the galaxy from any that might be artificial.

After the prototype machine is tested, Billingham estimates that in five years six machines capable of distinguishing signals from 10 to 100 million channels will be built. They will be hooked up to radiotelescopes in California, Puerto Rico, Spain and Australia which are now tracking the Pioneer and Voyager missions that flew past Saturn and Jupiter.

The new SETI research, by conservative estimates, will be a million times more extensive than all other searches for space signals combined, he said.

Despite skeptics who doubt that extraterrestrial intelligence exists, Billingham asserts that the search is justified on its scientific merits. This is why the National Academy of Sciences and the International Astronomical Union support the project, including the Congress which has provided initial funding of about $1.5 to $2 million a year for the next five years.

"Part of the reason for this support is based on the realization that we now have the technology to carry out a search for extraterrestrial intelligence," Billingham said. "There has been an absolute revolution in microelectronics, particularly with advances in large-scale integrated circuits and custom chips.

"And there's the innate curiosity that I think all human beings have about their own existence, their origins."

Individuals interested in enrollment information should contact the Office of Postgraduate Medical Education at (415) 497-5594.

HEMODIALYSIS AN ALTERNATIVE TO STEROIDS IN LUPUS PATIENTS WHOSE KIDNEYS FAIL

STANFORD—

Margie Sterner has nothing good to say about steroids.

"You bloat up like a fat pig when taking those drugs," said the slender, 35 year-old Foster City woman. "I never want.to go back to them."

But until 1978, Sterner was dependent on large doses of the steroid "prednisone" to control her lupus erythematosus, a disease of the immune system that can lead to severe joint pain, loss of hair, and damage to the heart, liver and kidneys. When the illness severely damaged her kidneys, traditional therapy suggested that her already high steroid dose be upped even further.

Instead, under the direction of her doctors at Stanford University Hospital, Sterner stopped taking prednisone and began hemodialysis, an unorthodox treatment for lupus patients. Within a few months, her kidney disease subsided without the use of steroids.

Simultaneously, most of Sterner's lupus symptoms disappeared, though Robert S. Swenson, associate professor of medicine at Stanford, emphasized that the onset of dialysis and remission in lupus were not causally related.

Sterner is one of 28 patients with lupus and severe kidney failure that Swenson, and Norman S. Coplon, a clinical faculty member, have studied in the last 13 years.

Results of the research, published in the Jan. 27 *New England Journal of Medicine* point to hemodialysis as an unforeseen option in dealing with the double curse of lupus and renal failure.

Although hemodialysis is a routine treatment for most patients whose kidneys fail, most physicians have spurned its use in lupus patients because of expense and an assumption that the physical and psychological burden of dialysis would do more harm than good to a patient already suffering from chronic disease, Swenson said.

-more-

But the Stanford study showed that the lupus patients responded well to dialysis. Eight of the patients showed enough improvement in kidney function that they could be weaned from hemodialysis—some for long periods of time.

"What we're trying to do is to get physicians to stop giving prednisone to these patients once they reach a certain point in their renal failure," Swenson said.

"Previously, physicians were working so hard to beat renal disease with prednisone that the patients succumbed to severe infection."

Prednisone is a valuable tool when physicians seek to "turn off the immune system," said Swenson. Recipients of heart and kidney transplants, as well as patients whose diseases stem from an overzealous immune system, can benefit from the drug. But, by stripping away the immune defenses, high doses of prednisone leave patients dangerously vulnerable to infections and other side effects, such as brittle bones and fluid retention.

Like Sterner, 25 of 28 patients in the study lost their lupus symptoms subsequent to the blood cleansing.

"However, we are not in any way suggesting that dialysis be considered as a treatment for lupus," Swenson said. "Hemodialysis only removes waste products of renal failure. It doesn't remove lupus toxins."

Why the lupus symptoms vanished remains a mystery, Swenson said, though the mechanism probably relates more to a chemical by-product of severe kidney failure than to dialysis.

About 110,000 Americans suffer from lupus, which most often affects women in their 20s and 30s. Only a small fraction of those, Swenson said, experience severe kidney failure, and would be candidates for hemodialysis.

WHY ARE THEY VOLUNTEERING?!

STANFORD—

In one clinical study at Stanford, volunteers are instructed to have a little more ice cream, cookies, and soda than they're used to for about three days before coming in.

"The high carbohydrate intake primes the pancreas for optimum response to our metabolic testing," explained Dr. Mark Rosenthal, associate investigator in gerontology.

"But some of our volunteers hesitate to comply, since they're very concerned with their weight and health." Rosenthal is studying the relationship between metabolism and physical conditioning in the elderly, by comparing the glucose tolerance of sedentary and athletic older men.

Why do these men, healthy and active with many other things to do, bother to join a study that requires them not only to eat foods they don't want, but spend two nights and two mornings in the clinical research center (CRC) at Stanford?

And what prompts participants in the Medical Center's many other clinical studies to make that first call to researchers in which they generously offer their time and energies?

The answers vary, say both researchers and volunteers, depending on the nature of the study, benefits to participants, and other factors.

"In our study," said Rosenthal, "the well-conditioned men seem to want to prove the benefits of their active lifestyles, while the sedentary ones are curious, and have altruistic reasons for participating in medical research."

Altruism—and the wish to do something important with their lives—is often a motivation, concurred investigators, especially with elderly and well-educated volunteers.

"I have a pacemaker, and I figure that somewhere along the line someone volunteered for research that made this possible," explained Eleanore Evans, a recent volunteer for the control group in a diabetes study. "Now if I volunteer, maybe someone else will benefit in the future."

Dr. George Liu and his associates conduct many studies on the various treatments of diabetes, under the direction of Dr. Gerald Reaven at the CRC. Many people who volunteer for control groups, Liu said, are Stanford-affiliated and, knowing first-hand the difficulties researchers face, "want to help us out."

Diabetic volunteers, he said, are often unhappy with treatments they've received thus far, and come to the study hoping to find something better. "They frequently become much more informed about their role in controlling the disease after joining us," Liu explained, thanks to the intensive teaching provided by researchers during testing.

-more-

"And they keep coming back for other studies," he added.

The studies that compensate volunteers are generally those in which no other personal benefits are offered. Often, for example, a study will provide its volunteers with a whole battery of medical tests and evaluations free of charge—an incentive that plays a large role in recruitment.

Liu, a physician specialist in the Division of Endocrinology, said some of his volunteers are people who have very early diabetes or lipid metabolism disorders, and the early screening and detection provided by the studies attract them.

Evans said she suspected she might have hypoglycemia when she first volunteered for the diabetes study. "But I found out I was fine and the doctors told me what I could do for the symptoms."

The investigators, she said, were very good about discussing her concerns and spending time with her. She said she probably wouldn't hesitate to call them again if she had a medical problem.

"We do build friendships with many of our volunteers and their families," said Liu.

He said all the studies his group conducts ask variations on the question: how much and in what combination will certain specific therapies help in controlling diabetes? Every protocol has its own time frame, he said, at the end of which the researchers evaluate how much improvement was made and what the next step should be.

What about risks to the volunteers? Under guidelines set by Stanford's medical committee for the protection of human subjects in research, volunteers for clinical studies must give "informed consent" as a requirement for participation.

Kathy Turner-Tamiyasu, R.N., now nurse manager of the gynecology/obstetrics clinic, previously held a position as research nurse in the Division of Clinical Pharmacology, under the direction of division chief Dr. Terence Blaschke. Ongoing research there examines age-related changes in the liver clearance of drugs metabolized by different pathways.

"It's not a dangerous study," she said, "but there *are* some risks associated with the drugs administered to volunteers."

The study includes compensation for the week a volunteer must spend in the CRC. "I found the money was the most common motivation," Turner-Tamiyasu said, adding that this could interfere with the informed consent process.

"People would decide in their own minds that they wanted to participate. So sometimes I felt they weren't listening attentively when I'd explain the details."

She described a similar interference that would occur when volunteers—especially older ones—had a "blind trust" in the medical establishment.

Turner-Tamiyasu also met people who needed a change in routine for a week, or to get away from a difficult personal situation. Some volunteers, she remembers, went so far as to spend their vacation time participating in the study—out of curiosity, perhaps, or because they needed the money.

-more-

"There's often an interplay of several motivations in the same individual," she said, adding that "clinical research is a very rough job. There's so much to go through with each person."

It starts with the initial screening, when potential volunteers first call the number they've probably read in a newspaper, heard on the radio, or obtained from a referring physician.

"We ask for a medical history," said Liu, "and look for certain criteria. Usually we get a far greater response than we need, and less than half the people who call end up in the study."

Turner-Tamiyasu said she never had too many phone inquiries, since "most we had to screen out right away. In the whole time I probably recruited 100 people, after talking to about 500."

After the phone call, if the volunteer sounds right, a meeting takes place for further explanation and physical examination.

At any point during screening or even during the study, Turner-Tamiyasu explained, volunteers are free to change their minds about participating. "Or sometimes during the physical exam something is found that disqualifies them that they didn't even know about."

But most volunteers who stick with clinical research end up feeling pretty good about it, whatever their initial motivations. They've helped others, and it's likely they've also helped themselves.

Ed Souza, photographer with the Stanford University News Service, was generally concerned about the state of his health when he volunteered for one of Liu's studies last summer. "I seemed to fit the criteria they were looking for since my father had had adult-onset diabetes," he recalled.

Souza thought he might have the disease, but instead he left the study reassured "that I still belonged in the control group." Meanwhile, he'd helped researchers gather data important to bettering treatments for those less lucky.

CLINICAL SCHOLARS' FUNDING RENEWED

STANFORD—

A two-year fellowship that permits physicians to expand their skills in fields ranging from law and economics to ethics and education was recently granted more than $1.1 million in a three-year funding renewal by the Robert Wood Johnson Foundation of Princeton, New Jersey.

Stanford and the University of California, San Francisco share both funding and administrative responsibilities for the Clinical Scholars Training Program.

Studies of the ethics and economics of clinical decision making, and computer modeling as an aid to cancer diagnosis are two projects newly funded by the fellowship.

Since its inception in 1974, the program has trained 41 physicians who are committed to clinical medicine, but have sought broader training related to the organization of health services, improvement of medical practice, and public policy in health, according to Halsted Holman, professor of medicine and director of the Stanford portion of the program.

Participants in the program attend seminars in such subjects as information sciences, sociology, cost-benefit analysis, anthropology, and systems analysis to lay the groundwork for subsequent research with faculty advisors from the Stanford, UCSF and UC Berkeley campuses.

Currently, seven Clinical Scholars training programs are funded by the Foundation across the nation.

Former participants are involved in academic medicine, government, and in the practice of medicine, according to the Foundation.

"The purpose of the program is to allow young physicians to develop skills in non-biological disciplines pertinent to the improvement of health care," Holman said. "Introducing non-biological disciplines into medical thinking and practice will not by itself resolve the problems of health care. Nonetheless, these disciplines provide understanding and methods which are essential to the search for better solutions."

A $20-MILLION PACKARD GIFT FOR NEW CHILDREN'S HOSPITAL

Editor's note: Story is released jointly by Children's Hospital at Stanford and Stanford University Medical Center.

STANFORD—

Gifts totalling $20-million for construction of the new Children's Hospital at Stanford have been pledged by David and Lucile Packard of Los Altos Hills, Stanford University President Donald Kennedy announced Monday (Feb. 7).

The gifts will be known as the David and Lucile Packard New Children's Hospital Fund and will be used by the board for the planning and construction of the new Children's Hospital. Under the terms of the pledge Stanford will provide an equal amount towards the project, primarily through additional fundraising.

"We want to help develop the finest Children's Hospital in the country and have it physically and intellectually connected to an outstanding university medical center such as Stanford," said Mr. and Mrs. Packard.

"The Packard commitment for this joint venture is the largest personal pledge either institution has received since their founding," Kennedy said. "It has given us a truly magnificent start for our comprehensive goal to consolidate all children's services in a new Children's Hospital."

The gifts, Kennedy added, will also complement the present efforts of the University to modernize Stanford Hospital and research facilities of the Medical School.

Packard, a Stanford alumnus and former trustee, is chairman of the board of Hewlett-Packard Corporation. Mrs. Packard, a Stanford alumna, is vice chairwoman of the current board of Children's Hospital at Stanford. Both have been known for their activities in support of education and community betterment.

-more-

The new Children's Hospital will be a $40-million building physically attached to Stanford University Hospital. It is expected to be ready for occupancy by a target date of May 1987. An agreement between Stanford and Children's Hospital has created a new corporation to operate a consolidated children's medical center, and a joint board was named recently to begin planning for construction. Mrs. Packard is also the vice president of the new Board.

Kenneth Sayre, of Menlo Park, chairman of the original Children's Hospital board and treasurer of the new board, said:

"This most generous gift caps a 15-year commitment that Lucile Packard made as a member of the board. That commitment is to develop superlative care for severely ill and disabled children.

"The Packards' contribution assures a successful beginning for the new Children's Hospital at Stanford."

Stanford and Children's Hospital have been running their pediatric programs from separate locations for years under the direction of the department of pediatrics of Stanford University School of Medicine. About 2,500 patients yearly are shuttled one mile across a busy thoroughfare between the hospitals for specialized treatment at Stanford.

"The separateness results in inconvenience to patients, duplication of services, and higher costs," explained Dr. Lawrence G. Crowley, chairman of the new Children's Hospital joint board and a University vice president for medical affairs.

"The consolidation will alleviate these problems and allow the two institutions to mount a comprehensive approach to the care of children in the community and region."

The new hospital will consolidate the 60 beds of Children's Hospital and the 44 pediatric acute medical-surgical and pediatric intensive care beds of Stanford Hospital. It will also house the Stanford-Children's Ambulatory Care Center, which provides 27 separate clinic services, including such specialties as cardiology, birth defects, oncology and child psychiatry.

The new children's hospital will continue to provide inpatient services in the 15 specialties now offered by both hospitals.

The existing Children's Hospital at 520 Willow Road in Palo Alto will continue to operate until the new building is completed.

The consolidation must also undergo the review process of state and local agencies.

PUBLIC LECTURES: ETHICAL ISSUES IN INTENSIVE CARE

STANFORD—

"Who Shall Live? Progress and Ethical Dilemmas of Intensive Care" will be the focus of the winter/spring 1983 Progress in Medicine lecture series, a community outreach program sponsored by the Stanford University Medical Center.

The season's presentations are:

- Feb. 16—"Intensive Life Support Systems: Present Practice and Moral Issues," featuring Dr. Thomas Raffin, assistant professor and assistant chief of medicine. His lecture will follow an introduction to the series by Dr. James Silverman, associate professor of radiology and chief of staff at Stanford University Hospital (SUH);
- Feb. 23—"Who is Saved?" with Dr. Myer Rosenthal, associate professor of anesthesia, medicine and surgery, and director of the intensive care units at SUH;
- Mar. 2—"Impact of the Intensive Care Unit on the Critically Ill Patient with Chronic Lung Disease," with Dr. Andrew Newman, clinical instructor of medicine at Stanford and director of the Bay Area Pulmonary Rehabilitation Program; and "Impact of the Intensive Care Unit on the Critically Ill Patient with Heart Disease," with Dr. Robert Sladen, assistant professor of anesthesia and associate director of the intensive care units at SUH;
- Mar. 9—"Newborn Intensive Care: Survival—What Price?" with Dr. David Stevenson, assistant professor of pediatrics and associate director of the Intensive Care Nursery;
- Mar. 16—"Who Suffers More—the Health Care Team or the Family?" with a panel including Silverman, Raffin, Jean Bronstein, R.N., assistant director of Nursing Service for the critical care region, and Aaron Smith, M.P.H., L.C.S.W., chief social worker in cardiology; and
- Mar. 23—"Ethical and Emotional Issues in the Care of the Dying Patient and Family," with Reverend Dr. Ernie Young, chaplain to the Medical Center and senior lecturer in medical ethics.

The Progress in Medicine lectures were initiated at Stanford in 1966 by Dr. Joshua Lederberg, then professor and chairman of the Department of Genetics, to provide an opportunity for leaders in academic medicine to share their insights and perspectives with the community.

Lederberg had observed: "The community has little opportunity to be informed of the exciting developments in medicine. Public understanding of these developments is of the utmost importance to social decisions."

All upcoming Wednesday evening presentations will take place in the Medical Center's Sherman Fairchild Auditorium, at 7:30 p.m. Admission is free, and seating is limited. There are no reserved seats, and no tickets will be issued. Early arrival is recommended to permit the best choice of parking and seats.

For further information, call the Medical Center's office of public events, at (415) 497-6389.

TREATMENT FOR BALDNESS BEING TESTED AT STANFORD; VOLUNTEERS SOUGHT

STANFORD—

A drug that stimulates hair growth will be studied for its safety and efficacy as a treatment for baldness by the department of dermatology at Stanford University Medical Center.

One of several sites in the country for conducting the study, the department announced its involvement to attract volunteers.

"This is not necessarily a cure for baldness. There are still a lot of unknowns," warned Dr. Elaine Orenberg, one of the coordinators of the study.

Specifically, the department is looking for up to 100 men in good health from age 18-49 with thinning hair or baldness to participate in testing Minoxidil, the active ingredient in Upjohn Company's antihypertensive drug, Loniten.

Stanford's study will last at least one year. Participants will be required to make monthly visits to the department for check-ups and evaluation. Preliminary physical testing will take place before individuals begin receiving the treatment, Orenberg said.

Investigators began considering the possibility of Minoxidil's effectiveness in treating baldness during clinical testing of Loniten, which was approved by the Food and Drug Administration (FDA) in 1979. One side-effect of the orally-administered drug is hair growth, as reported by about 80 percent of the patients taking the drug for hypertension. Once they stopped taking the drug, hair growth stopped. Investigators could not determine, however, who would experience hair growth, where they would experience it, or what type of hair would actually grow.

Investigators began to develop a topical ointment containing Minoxidil in 1977, to find out just how effective and how safe it is for use by balding men. With the FDA's approval, it is now being tested by applying it only to the bald areas. At Stanford, the study will be randomized and double-blind, with one group receiving the Minoxidil ointment and one group receiving a placebo ointment. The placebo will be replaced with the drug after four months.

Following completion of the studies—at Stanford and elsewhere—Upjohn Company will determine if FDA approval of the drug should be sought. Jan Auferdehide, spokeswoman for Upjohn Company, cautions men from hoping for a cure for baldness, however. "The FDA approval process takes 8-10 years on the average," she said.

Interested volunteers should call the department of dermatology at (415) 497-7964 between 1 p.m. and 4 p.m., Monday, Tuesday, and Friday.

Stanford Hospital Offered Medi-Cal Contract

STANFORD—

Stanford University Hospital officials were notified Friday (Feb. 4) that the hospital will be offered a contract to continue to provide care for Medi-Cal patients.

Stanford is among six hospitals on the Peninsula notified by telephone by the office of special negotiator William Guy that a contract will be sent for hospital review and signature. When signed by hospital officials, the contract will be effective March 1.

The specific conditions of Medi-Cal contracts are not made public.

In a joint statement issued today, Dr. Lawrence G. Crowley, president of the hospital; Sheldon S. King, executive vice president and director; and Dr. Donald Kennedy, chairman of the Board of Hospital Directors, said, "We are pleased that care can continue for Medi-Cal patients. We have long served patients who require the highly specialized services and treatment available at Stanford."

Hospital administrators had submitted a formal proposal for a Medi-Cal contract to the state negotiator last November. Under a law passed last year, the negotiator determines from the cost bids submitted which hospitals will be reimbursed for care of Medi-Cal patients.

Major services utilized by Medi-Cal patients at Stanford include high-risk obstetrical services, neonatal and pediatric intensive care, cardiovascular surgery and oncology/hematology and radiotherapy. In addition, SUH operates an emergency transport center for obstetrical patients, infants, and cardiac patients at risk.

About 15 percent of the hospital's total admissions are Medi-Cal patients. A high percentage are acutely ill referred from beyond the Peninsula area.

(Editor's note: Other Peninsula hospitals awarded contracts, according to the state negotiators office, are: Sequoia Hospital, Community Hospital of Los Gatos, O'Connor Hospital of San Jose, Santa Clara Valley Medical Center and Alexian Brothers Hospital in San Jose. Children's Hospital at Stanford is exempt from the Medi-Cal negotiations.)

CHEMICAL BOOSTER OF RADIATION THERAPY APPROVED FOR TESTS IN CANCER PATIENTS

STANFORD—

A drug developed by scientists at Stanford and SRI International which boosts the potency of radiation in shrinking cancerous tumors gained approval from the Food and Drug Administration this week for testing in cancer patients.

Called a "radiosensitizer" because it enhances the ability of radiation to kill tumor cells, the compound was first made and tested in 1978 by Martin Brown, associate professor of radiology, and William Lee of SRI International in Menlo Park, California.

Subsequent extensive testing proved the drug to be "highly effective" in eliminating certain tumors in laboratory animals without the usual toxic side effects of similar drugs, Brown said.

The FDA has now commissioned five U.S. medical centers to test the compound, named SR-2508, in human patients.

The drug works by mimicking oxygen, which plays a key role in radiation therapy, Brown said. In traditional therapy, beams of X-rays knife through cancerous tissue, tearing holes in DNA, the genetic material that enables the cell to live and reproduce. By locking onto the broken DNA, the oxygen, which is abundant in most cells, ensures that the damage will be permanent, and the tumor cells die.

But scientists realized 25 years ago that a kernel of cells that don't contain oxygen lurk within many, if not all, tumors, and these cells remain resistant to radiation.

"When you're dealing with cancer, killing 99 percent of the tumor isn't enough," Brown said. "You have to get it all."

To overcome the problem, some physicians have placed patients undergoing radiation therapy in chambers with pure oxygen at three times the normal atmospheric pressure, in hopes of coaxing more oxygen into the troublesome cells.

-more-

Another method involves using a different kind of radiation (for example, neutron or pi-meson radiation) that doesn't rely on oxygen to kill cancerous cells. Both methods improve the tumor eradication rate, Brown said, but are too expensive and, in some cases, dangerous.

In 1974, British scientists developed a compound that seemed a potential solution. The drug, named Misonidazole, mimics the effects of oxygen in the tumor cells, sensitizing them to radiation without affecting normal tissue. But animal and human studies show that doses of the drug high enough to be effective poison brain and nerve cells. Painful tingling in the hands and feet, hearing loss and disorientation have been prohibitive side effects of the drug.

Brown and Lee found that they could reduce the toxic side effects by modifying Misonidazole so that it was almost completely insoluble in fat. The new compound is thus unable to cross the blood-brain barrier, the fatty tube that encases and protects the brain and nervous system.

Studies in animals and human tissue showed that the new drug is just as effective as Misonidazole in enhancing the death of tumor cells, but is five to 10 times less toxic to nervous tissue.

"This drug is effective as a radiosensitizer in animals, there's no question about that," said Norman Coleman, the assistant professor of radiology who will lead the clinical study at Stanford."But it's not easy to tell how predictive that will be in human patients."

Approximately 150 volunteer patients across the country will be studied in the first phase of clinical testing, Coleman said. The centers collaborating to study the drug are five members of the Radiation Therapy Oncology Group: Stanford; Washington University, St. Louis, Mo.; University of California, San Francisco; the National Cancer Institute, Bethesda, Md.; and the Cross Cancer Institute, Edmonton, Alberta.

GETTING BACK TO WORK AFTER A HEART ATTACK

STANFORD—

Many mild heart attack patients are probably told by their doctors to stay home from work longer than is necessary, a Stanford University cardiologist believes.

"A good number of the lower-risk patients could likely hasten their return if they were given the confidence to do so," said Dr. Robert DeBusk, associate professor of clinical medicine and director of the Cardiac Rehabilitation Program.

Heart attack patients, he said, currently are advised to wait 80 to 90 days before returning to work. But his and colleagues' previous studies on more than 700 patients within three weeks of infarction have demonstrated that early exercise testing permits the distinction between high- and low-risk patients, said DeBusk.

His present study, funded by a new grant from the Robert Wood Johnson Foundation's Medical Practice Research and Development Program, builds upon those previous studies by carrying the question one step further: can the effective communication of information thus obtained through testing facilitate an earlier return to work for low-risk postinfarction patients?

The study will test a combined intervention—including both an occupational work evaluation and a behavior change program. "The intervention is designed to enhance patients' perceived health status," said DeBusk, explaining that this is a key factor in determining the patients' confidence and thus their return to work.

"Through the use of certain specific techniques, we hope to cut down to 30-50 days the amount of time the lower-risk patients need to stay home after heart attacks," he said.

The $150,000 grant will enable DeBusk and his colleagues to work with 600 male heart attack patients over the course of about two years. The researchers will attempt to detect changes in the time patients take to go back to work depending on such factors as age, state of employment, medical impediments, and mode of medical follow-up.

Moreover, DeBusk predicts that if doctors better identify high-risk patients from the start, they'll be able to more successfully intervene medically when necessary, while encouraging the lower-risk patients to get back on their feet sooner.

As the first step of his research protocol, a treadmill exercise test will be administered to patients three weeks after infarction. "This test serves a therapeutic as well as a diagnostic purpose," said DeBusk, "by demonstrating to patients their capacity for work."

-more-

The test allows doctors to establish a prognosis for each patient on which to base decisions. (In the event that abnormalities are found, medications or bypass surgery may be indicated.) A private counseling session will follow the test.

The behavior change program will be carried out by patients at home, DeBusk explained. "Physical activity, inability to cope with job stress, and smoking are three major areas of concern to postinfarction patients." These issues will be addressed by a program tailored to each patient's needs, making use of audiovisuals, advice-filled workbooks, and individually prescribed exercise (walking and jogging) regimens.

"Patients will monitor their heart rates, send us progress reports, and talk with nurses on the phone periodically. We'll revise our instructions based on what the patients tell us, and then we'll see them at the end of six months," DeBusk said.

A key question of the research, he added, will be whether or not the findings can be expanded to apply to a greater number of people. "For example, we will use these techniques only with patients 60 or younger during the study. But perhaps, observing older patients, we'll find that the same principles hold true for some of them.

"So we'll try to determine the relevance of our intervention, as related to different segments of the population."

Patients will be enrolled as volunteer participants in the study from five Kaiser hospitals throughout the Bay Area, DeBusk said. The project may begin as early as April.

DeBusk's research is one of 21 projects being funded under the Foundation's Medical Practice Research and Development Program. The grants, totaling $3 million, are aimed at improving medicine's capacity to assist impaired, acutely or chronically ill individuals in regaining or maintaining their functional abilities.

The present grants were made under a second annual round of projects funded under the Program. A total of 254 applications were received and reviewed by an expert panel for selection.

DeBusk, who received both his B.A. in history and M.D. degree at Stanford Universiy, has been on the faculty here since 1973. He is a Fellow of both the American College of Cardiology and the American College of Physicians.

The Robert Wood Johnson Foundation, the nation's largest private health care philanthropy, is committed to improving the quality, affordability, and delivery of health care in the United States. In the past 10 years over $400 million in grants have been made to institutions in support of health care projects.

STANFORD RATES HIGH IN NATIONAL ACADEMY OF SCIENCES ASSESSMENT

Stanford University's biological science graduate programs received high marks in a national study recently published by the National Academy of Sciences.

The study was not intended to rank the programs, but on a scale of 0 to 5, Stanford's biochemistry program scored 4.9, tied with Harvard and just behind Massachusetts Institute of Technology (MIT). The cellular/molecular biology and the microbiology programs scored 4.0.

"The study is extremely indicative of Stanford's present reputation in newly developing areas, and that the reputation will continue to grow," said Dr. Dominick P. Purpura, dean of the Medical School.

However, he noted that Stanford did not score among the top schools in physiology. "Establishing a strong physiology department is a target of the School's growth," he said. "It would be surprising if ten years from now Stanford was not included among the top ten physiology programs.

"It's nice to stand on laurels, but it's better to work towards meeting challenges," he added.

The study was sponsored by the American Council of Learned Societies, the American Council on Education, the National Research Council, and the Social Science Research Council. About 56 percent of the 1,848 academic biologists surveyed participated in the study. Many objected to the survey, which has been criticized in the past for "confusing prestige for quality".

Data collected by the study includes the number of faculty members in each program, the size of the university library, and the proportion of faculty receiving federal funds.

DRUGS OFFER HOPE AGAINST SUDDEN CARDIAC ARREST

STANFORD—

A scientist who has probed deeply into the molecular structure of human heart muscle believes that drugs could help prevent a sizeable proportion of the 500,000 yearly deaths caused by sudden cardiac arrest.

"In a sense," said Dr. William Clusin, "our research indicates that it is possible via medication available on the market today to make heart attacks 'safe.' At least we would be able to reduce sharply the occurrences of ventricular fibrillation (VF), which usually come without warning and often are nearly instantly fatal."

Clusin, a physician specialist in cardiology, has learned along with colleagues that drugs such as beta blockers and calcium blockers, can actually protect the heart from going into VF. This condition is characterized by uncontrolled spasms of the heart muscle and the subsequent failure of the organ to pump blood effectively.

Results of the Stanford scientists' research is scheduled to be published Feb. 5 in **Lancet**, a British medical/scientific journal.

"Beta blockers are administered routinely to relieve chest pains for persons suffering from heart disease. But our research has led us to believe that these drugs—or perhaps similar medication—should be given routinely to persons at risk of having a heart attack whether they have symptoms or not," Clusin said.

Past clinical studies have shown beta blockers—among the most widely prescribed drugs in the United States today—are effective at relieving the chest pain associated with a heart condition.

But what Clusin and his colleagues believe might be their most important potential was not known until very recently.

He said these drugs act to alter the movement of calcium within the cells to prevent the formation of abnormal electric currents which are the cause of VF. These injury currents have been known since the 19th century and can be recorded accurately on heart monitoring equipment.

For many years it was known that persons whose blood vessels became blocked by disease were prone to injury currents. But Clusin said it was not realized until recently that the injury currents may be triggered by abnormal accumulation of calcium within the heart muscle cells.

-more-

More importantly, the scientist said, research has shown that beta blockers and probably other drugs alter the flow of the calcium, thus decreasing the likelihood that an injury current will be generated.

Clusin and his colleagues observed the movement of calcium and the patterns and effects of injury currents by monitoring beating clusters of electically coupled chick embryo heart cells in tissue cultures. Then they confirmed their findings using live animal models in the lab and by reviewing available statistics about the effects on human patients of beta blockers.

"We must keep in mind that these drugs do relatively little to change the underlying cause of common cardiac illness—blockages in the arteries which arise because of diet, genetic factors or other causes. But by controlling the calcium movements in the heart, we are lessening substantially the possibility that an injury current will occur, triggering VF."

Prophylactic doses of medication offer a more practical solution for many patients than dealing with blockages surgically.

The risks of surgery pose their own problems, and in any case it may not be practical to identify the precise location of blockage in every patient, Clusin explained.

"In the past, researchers believed incorrectly that the only way to prevent the consequences of coronary artery blockages was either to relieve the blockages or to reduce the amount of oxygen consumed by the heart.

"We now realize that when the calcium content of the heart muscle cells is reduced by a drug, the muscle may tolerate a reduced blood supply without producing the abnormal electric currents that precipitate cardiac arrest.

"Therefore, it might appear prudent to administer such drugs to persons who appear statistically at risk of having a heart attack, even though they have no active symptoms.

Beta blockers can have side effects, such as fatigue or shortness of breath.

"However, there is another category of drugs called calcium blockers, which might avoid the side effects for some patients," said Clusin, adding that more research is needed before calcium blockers are administered routinely.

"But I think we do have enough research now to offer the possibility that doctors might prescribe prophylactic doses of beta blockers to their patients who are at risk."

In addition to Clusin, the recent studies of injury currents at Stanford were conducted by Dr. Michael Bristow, a physician specialist, and by postdoctoral fellows Maurice Buchbinder, Avery Ellis and Hardwin Mead. Collaborating was Donald Harrison, professor and chief of the division of cardiology.

KIDNEY TRANPLANT APPLICATION FILED BY STANFORD

STANFORD—

Renal (kidney) transplants could be resumed at Stanford University Hospital if an application filed Wednesday, March 30 is approved by the state Office of Statewide Health Planning and Development (OSHPD) in Sacramento.

The application must also be reviewed by the Santa Clara County Health Systems Agency (HSA) in San Jose.

Rex Jamison, professor of medicine and chief of the division of nephrology, said the program would provide the only renal transplant facility in Santa Clara County and would enhance and expand existing organ transplant research at Stanford.

Renal transplants were performed at SUH between 1965 and 1971, and then the specialized program became inactive.

"Recent developments in drugs to prevent rejection of organs and other research have increased survival of transplanted kidneys," Jamison explained. "This is an opportune time to revive the program."

In its application to reactivate the program, Stanford estimated that more than 80 persons under age 50 in Santa Clara County were waiting for new kidneys. Currently, these persons must seek transplantation at centers outside the area, often requiring burdensome travel or living expenses away from home, Jamison said.

Currently the two existing renal transplant centers in northern California—at University of California at San Francisco and Pacific Medical Center, San Francisco—are experiencing long waiting lists, according to Stanford's application to the HSA.

No additional hospital facilities would need to be built to accomodate the new program, since the hospital has the necessary specialized resources, said Patricia Stone, the health care planner responsible for processing the application. Jamison said a transplant surgeon and a transplant nephrologist would be recruited and that transplants could begin as early as January 1984 if the application is approved.

March 31, 1983

-more-

Among issues to be reviewed by the state agency are that the facility is medically and financially sound, and most important, that the project fulfills a health care need in the region, which is indicated in the application to be about 25 to 30 transplants a year.

The project would be a joint venture between the Department of Surgery and the Department of Medicine's Nephrology Division.

Stanford currently operates transplantation programs in hearts, heart/lungs, corneas and within the next few years, bone marrow.

"All of these programs complement each other, and the addition of kidneys would add to the research and instructional capabilities of the institution as well as improve patient care," Jamison said.

Research programs currently underway include efforts to use radiation to retard rejection, the body's natural response to "attack" and eliminate foreign tissue. This study is directed by Samuel Strober, chief of the division of immunology.

The heart and heart/lung transplant program, pioneered by Norman E. Shumway, chairman of the Department of Cardiovascular Surgery, is currently working with improved medication to control rejection while allowing tissue to heal. Cyclosporine is being used on an experimental albeit so far highly successful basis to control rejection of transplanted hearts. The drug, a fungal derivative, is being used for kidney transplant patients at other centers.

Stanford's existing nephrology program includes a hemodialysis unit, where about 40 patients undergo regular maintenance dialysis.

Jamison said that such treatment offers the sole alternative for some patients, particularly the elderly, but that transplantation offers the opportunity for a less restricted and more active lifestyle, despite the possibility of rejection.

Hemodialysis patients must spend two or three hours several times weekly immobilized while a machine removes waste products from the patient's blood.

He said even with the threat of rejection, transplanted kidneys usually are more effective than the dialysis machine.

Certificate of Need Filed for Stanford Hospital Modernization

STANFORD—

Plans for the modernization of Stanford University Hospital have been filed with state and local agencies for their review during the next several months.

Certificate of Need (CON) applications were filed March 30 with the California Office of Statewide Health Planning and Development in Sacramento and with the Santa Clara County Health Systems Agency in San Jose.

The CON process is required of hospitals seeking to renovate or expand their facilities, to ensure that a community need exists for the project.

The 400-page document includes financial feasibility studies, space plans, and extensive documentation of need for all aspects of the renovation and construction. It was prepared by the hospital's Office of Health Services Planning, in conjunction with the Hospital Modernization Project office and The NBBJ Group, an architectural and planning firm in Seattle and Palo Alto.

Included in the documents are financial and economic analyses and forecasts prepared by Amherst Associates Inc. of Walnut Creek.

The cost of renovation, new construction, equipment and fees is estimated to be about $114 million. The total cost will depend on financing conditions, but it is expected to be about $125.5 million.

The goal of the modernization is to upgrade the physical facility to meet the needs of modern medical care. Earlier studies have cited serious functional deficiencies that compromise the efficiency of the hospital and its future ability to provide quality patient care.

Because of inadequate space, the hospital has been unable to utilize all of its 663 licensed bed capacity. Some multi-bed patient rooms will be replaced with private rooms in the new construction. This will enable the hospital to accommodate a wider range of patient needs without adding to its licensed capacity.

-more-

3-31-83

The number of beds will be increased only in the 25-bed neonatal intensive care unit, which will be remodeled to accommodate 31 beds. State and regional studies have indicated that the need for care of critically ill infants is increasing in the region.

Project Director Elvia Garwood explained that the project is designed to take place in three stages.

The first stage calls for finishing the Phase I building, an expanison opened in 1978 but never completed.

In the second stage, a four-story, 349,000 square foot diagnostic and treatment wing and eight new nursing units will be constructed. These will be located north and west of the present building, with a connecting atrium to the present facility.

The new construction will increase the number of private rooms available, allow existing nursing units to be updated and remodeled, and provide space for moving about 90 beds from Hoover Pavilion to the Main Center.

A new surgical suite with new operating rooms will be built, and several hospital functions, such as clinical laboratories, will be consolidated in the new space.

In the third stage of the project, existing space in the original 1959 building will be remodeled as newly constructed space becomes available to relocate services.

When the project is approved at state and local levels, construction on the first step of the renovation could begin as early as next spring.

According to Ron Hill, director of Health Services Planning, the agencies will conduct an initial review of the CON documents to determine if they are complete. Detailed reviews are expected to last through the summer. Public hearings may be scheduled at local and state levels as part of the review process.

In addition to the CON, the hospital is preparing an Environmental Impact Report which will be filed with the City of Palo Alto later this year.

In the meantime, The NBBJ Group and the modernization project staff will be working with hospital departments, faculty and community physicians, to develop detailed plans and equipment needs.

NEAR-DROWNING VICTIM OK FOLLOWING HEROIC RESCUE BY FRIENDS

STANFORD—

The victim of a near-drowning incident is listed in stable condition at Stanford University Hospital (SUH) after a heroic rescue that reads like both a movie adventure and an endorsement for cardiopulmonary resuscitation (CPR).

Brian Miller, 18, is "doing well," according to Dr. Linda Bosserman, thanks to the immediate reaction of his eight friends who began administering mouth-to-mouth resuscitation after pulling him out of a river in which he was submerged for more than three minutes.

Bosserman said the immediate administration of CPR not only saved his life but also prevented any apparent brain damage.

"All the care we gave Brian was possible because of the early CPR treatment he received," Bosserman said. "Without that early care it is highly unlikely that he would have survived no matter what physicians did later."

Brian was admitted to the intensive care unit March 29, flown here from King City by Stanford's Department of Critical Care Transport. He was originally listed in critical condition because of potential complications of the heart and kidney and susceptibility to pneumonia, Bosserman explained.

However, Bosserman, a resident in medicine, said Brian was expected to be out of bed and walking by Thursday afternoon.

What Brian and his friends—all students at King City Joint Union High School—experienced in the remote, canyon-like area called the Shutins near King City, however, could easily have had a tragic ending.

It promised to be a great camping trip, recalled Brian's twin brother, Bruce, who explained the incident:

School was out for the week of spring vacation, and the weather finally cleared, making conditions ideal for the five-mile trek in from the road where the boys left their truck Monday.

Brian, Mitch Anderson, and Rick Bender were exploring caves near their campsite. The river had more than the normal amount of water in it due to the recent excessive rainfall, so the boys tied a rope around their waists as a precaution.

Suddenly, Brian stumbled and fell off a rock into the river. Mitch jumped in to grab him, only to be swept off by the current.

Back at the campsite, the rest of the boys heard screams. They ran to the caves to see Rick pulling Mitch out of the water.

Brian, however, was pinned under a rock. His head was submerged under water.

-more-

2-2-2 Bruce said he does not remember diving in the river with a knife to cut his brother loose. He managed to drag Brian's 6-foot-3-inch frame onto a rock. He was blue, Bruce recalled, and was not breathing. He had no detectable pulse, and was unconscious.

Peter Anderson, who works as a lifeguard during the summer, began shouting directions on how to start mouth-to-mouth resuscitation.

Together with Keith Knott and Gill Latham, they tried to breathe life into the still body.

Meanwhile, Doug Latham ran the five miles out to the truck, and began to drive into town. When the truck broke down, he ran the last 12 miles to the nearest farm. From there, he notified the fire department, sheriff, and military ambulance.

Brian began to throw up shortly after his friends began the CPR treatment. Not until 15 long minutes had passed, however, did he begin to breathe on his own again. Once he came to, he fought his friends violently, activity doctors said helped keep him alive.

Everyone Doug notified about the crisis set out immediately in rescue vehicles. Because of the location, however, none could make it to the cave site. Finally, two military medics hiked in. Navigating their way across the rocks, one fell in the river and hurt his back. The other reached Brian, and together with Peter's assistance, pulled him onto firm ground.

Darren Bryant had begun sending out smoke signals from the campsite to attract attention. A helicopter passed overhead after about an hour, but didn't land. It finally landed shortly thereafter.

Brian was lifted into the helicopter and taken to the Fort Hunter Liggett Dispensary. There he received oxygen and intravenous fluids, and was then transferred to George L. Mee Memorial Hospital in King City.

"Everyone in town rallied around Brian," said his mother of her friends in the small community. "They prayed for him all night."

Brian's physicians at Mee Hospital decided he should be transferred to a better-equipped hospital.

"He was brought to SUH because we are able to provide round-the-clock intensive care services under specialized physician and nurse supervision," explained Dr. Alvin Hackel, head of the transport service.

Brian's father accompanied him on the plane, while the rest of the family drove up to Stanford. And they don't plan to return to King City, his mother said, until Brian can go with them.

"When I saw Bruce he said, 'Mama, we did all we could. Did we do enough?' " she continued. He did indeed.

"We learned CPR during our sophomore year in high school," Bruce said. "At the time we thought it was just something to know. I never thought I'd have to use it. With Peter leading and all of our knowledge put together, we were able to save my brother."

"I'm thanking God every minute," added his mother.

And meanwhile, back at Stanford Medical Center, Dr. Myer Rosenthal, director of intensive care units, thanked CPR training in the schools.

"Some states routinely require this training in high schools. It might be a wise idea everywhere," he said.

GRANT TO HOSPITAL NURSING DEPARTMENT

STANFORD—

A grant to develop a research training program for practicing nurses has been awarded to Stanford University Hospital Nursing Services.

The three-year $600,000 grant from the Division of Nursing of the Department of Health and Human Services is the first such research training grant to a hospital nursing service department. Until very recently nursing research training was focused almost exclusively within university schools of nursing.

The project director is Duane D. Walker, associate director of Stanford Hospital and director of Nursing Services.

"We believe that nursing research is a powerful tool nurses can use to bring about changes in the delivery of health care," said Walker, "and research findings contribute to the scientific basis of nursing practice."

The Stanford nursing research program is directed at integrating clinical research as a part of nursing practice.

The research training will be designed for nurses who are daily involved in the care of patients. "They are in the best position to identify the problems that need study. They are also in the best position to collect data with the least disruption of patient care and to propose and implement solutions," according to Dr. Lois Welches, associate director of Nursing Services. She and Dr. Marianne Zalar, assistant director of Nursing Research, will administer the project.

Goals of the project are to develop educational programs in research methods, provide consultation support to nurses throughout the research process, and provide facilities such as research sites, libraries and data processing mechanisms. Research courses and seminars will be conducted for beginning and intermediate level nurse researchers.

3/29/83 -more-

The training will be offered to practicing nurses from a consortium of eight Bay Area hospitals and a visiting nurses association, all located within a 35-mile radius of Stanford.

The consortium was established in 1980 under Walker's leadership.

The nine agencies in the Research Consortium of Hospitals are: Stanford University Hospital, Children's Hospital in San Francisco, Mount Zion Hospital in San Francisco, El Camino Hospital in Mountain View, Mills Memorial Hospital in San Mateo, San Francisco Veterans Administration Hospital, Palo Alto Veterans Administration Hospital, Children's Hospital at Stanford, and the Santa Clara County Visiting Nurses Association.

Nurses from each of these institutions can join together to conduct studies over a far larger study base than would be possible alone.

A major problem encountered in clinical research, according to Welches, is obtaining an adequate study sample, since the patient's stay is so short. Data collection in all of the consortium agencies will yield a far greater sample as well as enable the researchers to generalize findings.

For example, a research proposal was developed at Stanford to compare two methods of treatment for decubitus ulcers, or bed sores. Nurses have the primary responsibility for the prevention and treatment of decubitus ulcers. Many methods of care are available, but no definitive treatment has been identified.

Stanford nurses collected data on two alternative treatments and made recommendations based on healing time, nursing time, and cost factors.

The Research Consortium has expanded this pilot study and data is currently being collected simultaneously in six of the consortium agencies. Results based on the larger study may lead to a change of treatment policy and greater impact on quality of patient care.

The Research Consortium is the only group of its kind in the country. "Hospitals throughout the country have asked to join," said Walker, "but more cannot be accommodated during the pilot phase of the project." He hopes, however, that the group will serve as a model for others.

Walker is committed to the need for nursing research within the hospital setting. "It is essential that we critically and systematically examine our practice if the optimal quality of care to patients is to be ensured," he said.

NEW GROUP FORMED TO CHECK CHARGES OF RESEARCH FRAUD

STANFORD—

A new committee to evaluate allegations of research fraud has been established at Stanford University School of Medicine, Dean Dominick P. Purpura announced in a March 4 letter to faculty members.

Though instances of verifiable fraud have remained "vanishingly small" nationally, Purpura said, "even a rare instance of scientific fraud damages science as an intellectual enterprise, violates expectations of fundamental trust and diminishes all who take special pride in a commitment to the pursuit of truth and excellence."

"It is sufficient for these reasons that we undertake a program for dealing with allegations of academic fraud swiftly, fairly, and honorably," he said.

Both the American Association of Medical Colleges and the National Institutes of Health have, in recent months, urged medical schools nationwide to establish such committees in an effort to curb research fraud.

While a protocol for disciplining an errant researcher has long been established at Stanford, evaluating the legitimacy of allegations has been "tortuous" in the past, Purpura said. "We now have a framework within which we can examine and resolve allegations swiftly."

Anyone who believes an act of academic fraud has taken place at the medical school should promptly contact the dean, who will notify the provost and president of the university, and refer the matter to the "Committee on Ethical Scientific Performance" for preliminary study, Purpura said.

A summary of the charge and results of the committee's findings are to be forwarded to the provost within four weeks of the initial allegations. The president then will determine whether formal charges should be filed in accordance with the process set forth in Stanford's long-standing "Statement on Faculty Discipline."

Both the dean's and president's inquiries will be confidential, to be made public or disclosed to research sponsors at the discretion of the president.

Members of the Committee on Ethical Scientific Performance are: Jack Barchas, professor of psychiatry; Roland Ciaranello, associate professor of psychiatry and chairman of the school's faculty senate; John Collins, professor and chairman, department of surgery; Stanley Falkow, professor and chairman, department of medical microbiology; David Korn, professor and chairman of the department of pathology; and Kenneth Melmon, professor and chairman of the department of medicine.

PATIENTS SHOULD PLAY A PRIMARY ROLE IN DECISION TO "PULL THE PLUG"

STANFORD—

Adult patients slipping toward death in hospital intensive care units need help, but they must be treated as adults, not children, cautions a hospital chaplain.

When the kidneys, heart, and lungs begin to fail and death is imminent, there is often a temptation to make decisions for the patient, wrenching from him the last shreds of autonomy, said Ernle Young, chaplain at Stanford University Hospital, and lecturer in medical ethics at the School of Medicine.

"The form of the relationship between care-givers and patient ought not to be 'parent-child' but 'adult-adult,' Young said in a public lecture Wednesday evening (March 23). "This means that paternalistic decisions on the part of caregivers ought to be the exception rather than the rule. And the exception always requires justification."

In the last in a series of community lectures on progress and ethical dilemmas of intensive care, Young focused on the dying patient, and the ethical and emotional issues that permeate his care.

"Even though the patient may not be able to speak or to articulate anything, one of the skills that has to be acquired in the intensive care setting is learning to communicate with people who can't verbalize what they want to say," Young said in a related interview.

"One of the things you do is focus on nonverbal forms of communication. Another thing you can do is intuitively understand what they are trying to say, and express it for them. You say, 'is that how it is?' and you get a signal—maybe a squeeze of the hand—that says 'yes, that's what I'm feeling.' When the person is conscious, all of these decisions about life and death really do need to be checked out with them."

In theory, permitting a conscious, competent patient to decide when artificial life support should be discontinued "sounds fantastic, but in practice is often very difficult," Young said.

3-25-83

-more-

"Some of us here tonight were up in the adult ICU earlier today where a lady, who was still conscious and who was party to the decision that aggressive treatment should be withdrawn, is now dying.

"It is a very much more difficult thing for caregivers and family alike to (be with) such a person in her dying than it would be if she were unconscious and out of it altogether," he said. "She is staring death in the face with enormous courage and peace."

When the patient is an infant or unconscious, and can't be consulted, the thorny decision shifts to the family and health care team. Though the family should assume an important advisory role, the physician and other members of the critical care team, must take ultimate responsibility for deciding when to halt life support, Young said.

Such assertiveness on the physican's part might be considered paternalistic, Young admitted, but he added that the "irreversibility of disease is a uniquely medical decision."

But even the medical decisions are not always clear cut, he said, describing the case of a man hospitalized for internal bleeding, who underwent 16 operations during his 14 months in Stanford's intensive care unit, and acquired a bill of $750,000 before his death.

"How long do you keep on going before you decide, 'Okay, we've given it our best shot, the time has come to quit?' " Young asked. "In this case, the patient died before we quit—14 months and much suffering later."

Families who fear guilt feelings after assenting to termination of aggressive life support for a person who has no chance for recovery need to realize that "it's not the withdrawing of the support that kills a person, it's the underlying disease process," Young said.

HOSPITAL AUXILIARY CELEBRATES LANDMARK

STANFORD—

The Auxiliary of Stanford University Hospital has passed the $1 million mark in contributions to the hospital since 1960. The record number of gifts was reached with this month's approval of a $28,000 project to fund *Lifeline*, a home emergency response program for the elderly and chronically ill.

Celebration of the landmark highlighted this year's Auxiliary reception, given Monday evening at the Faculty Club by the board of directors and administration of Stanford University Hospital (SUH).

"I think it's very special to have given $1 million," said Auxiliary president Dee Gaynor to her co-members on accepting a plaque from SUH director and executive vice president Sheldon King. "We'll hang this proudly," she said.

Most of the money the Auxiliary dispenses is raised at the hospital gift shop, and almost all of the gifts are for patient care, approved upon department request. Examples of gifts this past year were a fluorescent microscope for the Department of Pathology, Social Services' patient care emergency funds, and two fetal heart monitors.

"We've worked very hard to get the sorts of things we want for the hospital," Gaynor concluded. *Lifeline*, King noted, will help keep the elderly safer at home and out of nursing homes longer. Components of the community service system should arrive at SUH within a month.

Gaynor, who has served as Auxiliary president for 1982-83, also received the gift of an antique white brass cooking pot from Korea, called a "shinselo," in honor of "her quick wit, compassion, and ability to forge ahead enthusiastically," as was inscribed on the pot.

Gaynor praised the efforts and cooperation of all Auxiliary members, encouraging them to lend the same support to her successor, Donnie Ellington, for the coming year. The total number of volunteer hours as of March, 1983, was impressively tallied at more than 1.6 million.

Other speakers at the well-attended event—which included cocktails, hors d'oeuvres, and a background of live music by the Benji Austin Quartet—were Dr. Donald Kennedy, chairman of the SUH Board and president of Stanford University; and Dr. Lawrence Crowley, vice president for medical affairs and president of the hospital.

Kennedy remarked, "I am here to extend the university's deepest gratitude and my own to all of you for all you do for the hospital."

The March 21 event was arranged by the Department of Community Relations, under the direction of Jeanne Kennedy. Buttons and balloons commemorating "our Auxiliary—one in a million" were distributed. This was the third time a reception was held for the Auxiliary, the first having been in 1980.

RODNEY MILLION NAMED CHARLES E. CULPEPER VISITING PROFESSOR

STANFORD—

New combinations of treatments for aggressive cancers of the head and neck will be highlighted in a lecture given March 31 by Rodney Million, the 1983 Charles E. Culpeper visiting professor at Stanford University School of Medicine.

Million, professor of radiology and director of the division of radiation therapy at the University of Florida College of Medicine in Gainesville, will speak on "The Results of High Dose Radiation Therapy and Surgical Salvage for Carcinoma of the Pyriform Sinus" at 5:15 p.m. in room M-112.

Although head and neck cancers are responsible for only seven percent of all cancers, they can be among the most vicious, said Malcolm Bagshaw, chairman of Stanford's department of radiology.

Surgery to eradicate the cancer can require cutting through the jawbone, or removing the larynx.

"Any supplemental treatment, such as radiation therapy, that can reduce the extent of the surgery is very useful," Bagshaw said. "Dr. Million is a distinguished researcher who has made great contributions in this area—demonstrating how radiation and surgery can work together to eliminate the cancer. He also has made important contributions in identifying some of the adverse effects of radiation, particularly on the eye."

Million will deliver three lectures, all open to the public, during his three-day visit to the Medical Center. "The Effects of Radiation on the Normal Eye and Optic Nerve" will be held on Wednesday, March 30 at 5 p.m. in room M-106, while "Experience with Preoperative Radiation in Rectal Carcinoma" will take place on April 1 at 8 a.m. in room S-092.

A 1954 graduate of Indiana University Medical School, Million has been a faculty member of the University of Florida College of Medicine since 1964, and has published more than 40 papers on cancers of the head and neck. In 1979 he was awarded the Grubbe Gold Medal award by the Chicago Radiological Society and, in 1982, garnered the Distinguished Alumnus Award from the M.D. Anderson Hospital and Tumor Institute in Texas.

This is the third year of a five-year rotating visiting professorship at Stanford sponsored by the Charles E. Culpeper Foundation of New York. The departments of surgery and medicine hosted the first two scholars.

The Foundation primarily supports health, education, science and technology programs, in addition to offering grants to support arts and letters, youth activities, administration of justice and Native American affairs.

PATIENT HEARTS STUDIED IMMEDIATELY AFTER SURGERY

STANFORD—

A blend of modern technology and cardiovascular research will be giving doctors a new look at the heart in much the same way that a dynamometer helps mechanics analyze engine function.

Dr. D. Craig Miller, associate professor of cardiovascular surgery at Stanford University School of Medicine, recently received a three-year, $491,334 federal grant to study the changes occurring in cardiac function immediately after open heart surgery.

The study is a collaborative effort with the Palo Alto Medical Research Foundation (PAMRF), where Dr. Neil B. Ingels Jr., Ph.D. and engineer George Daughters earlier developed the underlying technology for the research.

"It's difficult to believe, but we still are ignorant of certain changes in left ventricular function and bioenergetics which occur immediately following cardiac surgery," Miller said.

"We can partially compensate for the unknowns by extremely diligent monitoring. But better knowledge of these changes and responses to different drugs and interventions should translate eventually into better patient care," he added.

Specifically, Miller said, the study might answer questions about the optimum dose of many different drugs to be administered to patients in the crucial hours after surgery.

"We will be taking a precise look at the blood volume and pressure in the left ventricle," where blood is propelled from the heart out to the body, said Miller.

"Additionally, we will be measuring 'on line' coronary blood flow and the amount of oxygen used by the heart," he added.

Two "gadgets," actually serious technological advances both refined at PAMRF, are central to making the study possible, Miller said.

First is an X-ray machine which can be wheeled to the patient's bedside in the intensive care unit shortly after surgery. This device was modified specifically for the study to incorporate high resolution and high power in a large screen format, while simultaneously retaining sufficient portability and compactness to be used at the bedside.

Unlike traditional X-ray—which requires cumbersome equipment to record the picture on film—the technique employed in the current study permits a series of pictures to be recorded on a 10-inch video camera which is linked to a high quality video disk drive unit.

The data on the video disk, which includes blood pressure and other data as well as images, is later transferred to a permanent (dedicated) computer system.

A total of 1,200 frames, taken at the rate of 30 per second, can be recorded and eventually transferred to the main computer system for analysis.

Studies can be carried out every four to six hours after surgery for the first 36 hours and then again after the patient recovers.

"This enables us to track the beating of the heart muscle, since we will be able to see movement much like a television or motion picture," Miller explained.

But tracking the precise motion of soft tissue such as the inside of a heart is impossible without using a dye or other material injected directly into the left ventricle. So the researchers have developed a second technological aid. This involves a series of seven tiny, almost microscopic markers, which are placed in the wall of the heart during surgery.

Made of a rare metal called tantalum, these markers are visible in the x-ray pictures, and will not be felt by the patient, Miller said.

The pictures actually will be images of the markers moving, but by being placed strategically, they will offer an accurate blueprint of the changes in the left ventricle's size every 1/30 of a second, Miller said.

The markers have already been placed during the past eight years in heart transplant and other patients at Stanford, using bioengineering and computer techniques developed by Ingels and Daughters at PAMRF.

In the current tests, Miller said he hopes to record data from one patient per week undergoing either cardiac valve replacement or coronary bypass grafting. These patients will have been fully briefed about the study and will have signed a consent form agreeing to participate in the study.

"What we are learning may be analogous to the information which a mechanic receives from a dynamometer. We don't anticipate that these studies will ever become a routine clinical test, but as a research tool, it will enable us to gain physiological information never before possible in man immediately after surgery. This should improve care for open heart surgery patients everywhere in the future."

"In the past we have not been able to study precisely and instantaneously what is occurring in the left ventricle immediately after surgery. Such information could only be gained by invasive cardiac catheterization techniques which simply aren't feasible to perform on patients in the intensive care unit every few hours during the first two postoperative days," Miller explained.

The grant from the National Heart, Lung and Blood Institute includes a $75,972 per year subcontract to PAMRF for bioengineering support and mathematical analysis of the myocardial marker data.

Collaborators in the current study include Miller's colleagues in the Stanford Department of Cardiovascular Surgery, including Dr. Edward Stinson, Dr. Philip E. Oyer, and Dr. Edwin Alderman, a cardiologist.

Other researchers in addition to Ingels and Daughters are Geraldine Derby, research nurse; Carol W. Mead, senior research assistant at PAMRF; Anne Schwarzkopf, Stanford research assistant, and cardiology fellows Dr. Steve Oserle and Mike Fowler.

STANFORD PROFESSOR WINS AWARD

STANFORD—

Dr. Saul A. Rosenberg, professor of medicine and radiology at Stanford University School of Medicine, is the first recipient of the Department of Medicine's Albion Walter Hewlett Award.

Dean Dominick P. Purpura announced the award at this morning's (March 24) medical grand rounds.

Rosenberg "has been recognized by his colleagues as the epitome of the academician dedicated to discovery in the biological sciences and to the sensitive and scientific application of such new knowledge in the effective treatment of human disease," states the award certificate.

The award was established last spring by the Department of Medicine to honor academic physicians who have advanced scientific knowledge and applied it to patient care. Dr. Albion Walter Hewlett was an internationally known professor of medicine and leader in clinical investigation at Stanford from 1916 until his death in 1925.

"There is no greater honor than to be recognized by your own," Rosenberg said. "Nothing is as important, appreciated, or difficult as being recognized by your own family, especially those who are not in your precise field. It gives me a special sense of satisfaction, as well as a special challenge to be the appropriate model for this award so the tradition can continue."

Rosenberg, a leading oncology expert, has received international acclaim for his research on Hodgkin's disease. He and Dr. Henry S. Kaplan, D'Ambrogio Professor of Radiology—both pioneers in the field—have made dramatic advances in the diagnoses and treatment of the disease, which have led to better than 80 percent survival at five years for all stages of the disease. Seventy-five percent of the patients are permanently cured, according to published figures.

Rosenberg was among those who spearheaded the development of oncology as a specialty of internal medicine. He is chief of the Division of Oncology at Stanford, which was established in 1965. He is also director of the Debbie Probst Oncology Day Care Center, a treatment center for cancer patients, which opened in 1978.

3-22-83

-more-

Rosenberg has also received the Henry J. Kaiser Award for Excellence in Teaching, and was the first recipient of the Arthur Bloomfield Award for Excellence in Teaching in Clinical Medicine. Medical education is one of his primary concerns—he took a year-long sabbatical to study the problems of premedical students competing to get accepted to medical school.

A native of Ohio, Rosenberg received his undergraduate degree and medical degree at Western Reserve University.in 1953. The first time he applied to medical school he was rejected; the second time he was told he could come work in a laboratory for a year, after which his application would be reviewed. The laboratory was involved with radiobiology research, which spurred his interest in radiation as a treatment method for malignancy. He also enjoyed internal medicine during medical school. Upon graduation, he decided the way to combine his interests was to specialize in oncology. But first, he had to create the specialty.

He trained at various hospitals that offered radiation therapy and cancer programs, and came to Stanford in 1961 to work with Kaplan. Their mutual interests in radiation therapy and cancer led to their research in Hodgkin's disease. And the support of the Department of Medicine, Rosenberg said, led to the development of the oncology specialty.

"Perhaps an equal accomplishment to the research in Hodgkin's disease is that of establishing the field of medical oncology as a respectable, successful field in internal medicine. I have had a major role in that at Stanford and we have been one of the strongest programs in the country. On a national scene, I've probably helped more people by helping establish this field and training physicians in it," Rosenberg said.

The Hewlett Award consists of a certificate, a silver medallion depicting several figures from a sculpture symbolizing the award, and funds with which to buy books for the Hewlett Library.

The sculpture, housed in Stanford University Hospital's main lobby, was unveiled last spring. It depicts "man—his isolation intensified by disease—and the evolution of his integration with society through the intervention of the physician," according to Dr. Kenneth Melmon, chairman of the department of medicine.

All local members of Hewlett's family, including son William; daughter Louise Nixon; and grandchildren Walter, James, and William Hewlett took part in the day's ceremonies.

WOMEN AND HEALTH: PUBLIC LECTURES

STANFORD—

A Friday noon lecture series on *Women and Health* will be presented this spring at the Stanford Medical School by the division of family medicine.

Open to the public free of charge, the scheduled lectures are:

- April 1: "Transforming Stress into Creativity," with Margaret Buck, John F. Kennedy University;
- April 8: "Living with Questions," with Alla Bozarth-Campbell, Episcopal priest, gestalt therapist, feminist poet;
- April 15: "Women's Health Movement," with Sheryl Ruzek, M.P.H., Ph.D., postdoctoral research fellow in epidemiology, U.C. Berkeley, and core faculty, Women's Roles in Health and Healing, U.C.S.F.;
- April 22: "Abusive Images of Women in Mass Media and Pornography," a presentation by WAVPM (Women Against Violence in Pornography and Media);
- April 29: "Women and Women's Health Care: Legal and Professional Barriers," with Rosemary Mann, C.N.M., teacher of women's health care and law student;
- May 6: "Maternal Alcoholism and Family Life," with Genevieve Ames, Ph.D., Fellow NIAAA, medical anthropologist, teacher and researcher, Alcohol Research Group, School of Public Health, U.C. Berkeley;
- May 13: "Barriers to Health Care for Older Women," with Donna Ambrogi, managing attorney, Bay Area Law Center on Long-Term Care, coordinator of Care Giver Task Force, Older Women's League;
- May 20: "Sex Role Development," with Julie Olsen Edwards, director, department of early childhood and family life education, Cabrillo Community College;
- May 27: "Women and the Nuclear Arms Race," with Dr. Deborah Gordon, family physician, co-president, Redwoods chapter, Physicians for Social Responsibility.

A discussion group with case presentations will be held for enrolled participants following each lecture, from 1:15 to 2 p.m., with the speaker, as well as research assistant Marita Grudzen, Jeanne DeJoseph, C.N.M., Ph.D., and Dr. Judith Martin from the Division of Family Medicine.

The lectures will be held from noon to 1 p.m. in room M114. For further information call (415) 497-7043 between 8 a.m. and noon, or (415) 497-6431 from 2 to 5 p.m. weekdays.

WEIGHT-LOSS CAMP FOR TEENS

STANFORD—

Stanford's behavioral medicine program this year is again offering a summer weight-loss day camp for teen-agers, ages 12-17, on the University campus.

Encouraging campers to take charge of their own weight management, the program will teach them to lose weight safely through eating and exercise patterns that promote permanent weight control.

Intended specifically for teen-agers, the camp will allow them to have fun and develop skills while slimming down. Included will be group seminars in behavioral change techniques and nutrition education; aerobic activity, tennis, swimming, and other recreational activities; group lunches on campus; and weekly seminars for parents.

(An important feature of the camp is consistent weight-loss management achieved through the intensive day program combined with parental support at home.)

Faculty will include members of the behavioral medicine program of the School of Medicine.

Two sessions will be offered, and a fee will be charged. The first session will run from June 20 through July 14; the second from July 18 through August 11. Both will take place Mondays through Thursdays, from 9 a.m. till 1 p.m. Campers may register for one or both sessions.

Early enrollment is recommended, as space is limited. For further information call Dr. Mary Southam, at (415) 497-5065.

HARVARD SCHOLAR TO DISCUSS DIZZINESS

STANFORD—

Understanding dizziness will be the topic of the seventh annual George S. Kiperash Lecture on Thursday, March 24, at Stanford University.

The lecture, "Labyrinthitis and Endolymphatic Hydrops, Cause and Effect," will be delivered by Dr. Harold Schuknecht, professor of otology and laryngology at Harvard Medical School.

Labyrinthitis, or infection in the middle ear, is among the leading causes of dizziness, explained Dr. Martin Hopp, assistant professor of otolaryngology/head and neck surgery at Stanford. Another leading cause, endolymphatic hydrops, or the enigmatic "Meniere's Disease," is characterized by severe recurrent dizziness, he said.

The public is welcome to attend the lecture, sponsored by the Division of Otolaryngology/Head and Neck Surgery, to begin 8 p.m. in the Forum Room, Meyer Library on campus. Continuing medical education credit is available.

Schuknecht is a well-known ear disease specialist who has been instrumental in developing new surgical treatments for dizziness disorders. These treatments, now available as well at Stanford University Medical Center, will also be discussed in his lecture.

A native of South Dakota where he received his bachelor's degree in 1938, Schuknecht had his medical training and residency at the University of Chicago, where he later served on the faculty. He served at the Henry Ford Hospital in Detroit from 1953-61 before joining the Massachusetts Eye and Ear Infirmary (Mass. General Hospital), where he is now chief of otolaryngology.

Schuknecht has been the president of four otolaryngology societies, served on the editorial boards of five professional journals, and published widely throughout his career.

The Kiperash Lecture was established to bring national and international figures to Stanford and to enhance continuing education and residency training. It is named after George Kiperash, Jr., a former Stanford patient and native of San Jose.

For further information regarding this year's lecture, call (415) 497-6891.

THE SOCIALIZATION OF MEDICAL STUDENTS

STANFORD—

The desire to be a good doctor—warm, sensitive, caring—is part of every medical student's dream. Yet students at Stanford University School of Medicine say most medical schools do not encourage the development of these very qualities. In fact, many students learn to suppress, and even eliminate them during their medical education.

Now, for the first time since the Abraham Flexner report on medical education in 1910, medical educators nationwide are questioning the process that leads to the denial of the emotional side of medicine by its practitioners.

The trend starts early on, according to Dr. Saul Rosenberg, professor of medicine. During a year-long sabbatical researching the effects of the "pre-med syndrome," he found that in their competitive quest to get accepted to medical school, high school and college students often sacrifice liberal arts courses for more science courses, and extra-curricular activities for more hospital or research laboratory work.

And it continues on into internships and residencies, says Dr. Harvey Weinstein, assistant clinical professor of psychiatry, a time when physicians-in-training—no longer students but not yet fully accepted as doctors by the medical community—have no group support but more than their share of responsibility for patient care. With strenuous work schedules, often forcing them to stay up for days on end and controlling their lives, studies show interns and residents are the most susceptible for impairment.

It's the time in between, however, he continues, the average of four years spent in medical school, that the qualities that will last through the students' medical careers are planted and developed. They come to medical school, considered the cream of the crop and used to excelling in all they take on, and suddenly find themselves at the bottom of medicine's hierarchical ladder. Faculty treat them as if they know nothing, and the relationship, many say, is like that of a parent and child.

"Medical school and training is regressive. It pushes people backwards in time in a sense, into a situation where they're constantly told they don't know enough and have to be taught," Weinstein says.

"There's a terrible fear of not being a good doctor. Everyone wants to be one but no one knows what it is exactly," says Nancy Harris, fourth-year student.

And so, to ensure their chances of being a "good doctor," students give up just about all extra-curricular activities, substantially limit relationships, delay having children, and submit themselves to the stresses of too much to do and learn in not enough time. Faculty encourage them to "eat, sleep, and breathe medicine."

3/15/83 -more-

The academics, students agree, are the easier part of medical education. It's learning how to be a doctor—the socialization process—that makes medicine one of the most difficult careers.

"Medicine is taught as a left-brain, scientific, factual profession," says Dr. Peter Finkelstein, who completed his psychiatry training at Stanford. "The quality of individuals' outside lives, and their internal thinking doesn't hold much value. In medicine you get credit for knowing and doing everything, and not for feeling."

"Most physicians learn to shut down their feelings," says Michael McGee, fourth-year student. "Their emotions are in a little box in a corner of their minds, unavailable to them. They lead their lives mechanized, they know the techniques of their profession, they're consumed by the amount of time they spend at it. They haven't integrated the meaning of their profession with their work.

"Here we are, learning to deal intimately with peoples' lives. So, we should be humane, caring and sensitive. But when do you learn to start caring? From a few lectures in a course? You learn how to be sensitive and caring from the environment. Here you see very uncaring, status- and hierarchy-oriented doctors. It's the whole medical machismo syndrome of being the superhuman, all-knowing, tough doctor. If you're going to care for other people, the reasoning goes, you can't be weak. And feeling is considered weak."

Students begin to pick up on the machismo from day one.

"The first thing you do in medical school is walk into the anatomy lab," describes Sally Rubenstone, fourth-year student. "No one ever tells you there are going to be 40 dead bodies in there. It's shocking. But no one says that, so you think you can't show that it bothers you. Then you just start slicing these bodies open. Never once during the entire course does someone say anything. You learn from early on you're not supposed to react."

"Students pick up a lot of norms right away: a preoccupation to master cognitive material, cooperation, teamwork, good spirits," says Finkelstein, who has been observing students' responses for four years as part of a research project.

"Superficially, someone looking in on an anatomy laboratory may think things are okay. There's a lot of things going on they don't feel comfortable with, but they hesitate to express these feelings," he says. It may be that the process of medical training promotes 'psychic numbing,' so to speak."

This psychic numbing—not connecting what students see with what they feel—is propagated by not giving students the opportunity or the time to assimilate their experiences, Finkelstein adds.

"To truly produce a reflective, deep physician, the level of assimilation needs to be much greater. There is no opportunity to do that, he explains.

"The enemy of emotion is lack of time," says Bruce Bowman, a resident at Stanford University Hospital.

After two years of being overwhelmed with facts, students switch course and are thrust on the hospital's units where for the first time, they deal directly with patients. This, they say, is a whole new ball game.

-more-

On one hand, many patients look up to the students as doctors, responsible for their care. But again, as prescribed by the hierarchy, the students are repeatedly told by the powers above they know nothing, Harris explains. They are grilled on facts in front of patients, other students, interns, residents, and attending physicians, often humiliated and intimidated if they do not know the answers to questions they're asked.

"Learning how to assume that doctor role—when to enter a room, where to stand, how to present a case—no one helps you at all," she says.

Adding to their dilemma is justifying patient care, when they may not agree with the prescribed treatment.

"The hardest thing was to deal with my emotions about moral and ethical issues," Harris says. For example, she recalls, she once helped care for a 94-year-old man with terminal pneumonia. "He came in at 5 p.m. one day and was dead by noon the next. The doctors decided to give him round-the-clock enemas to lower his potassium levels. I was the only doctor who stayed with him practically around the clock. He was moaning, wimpering, pleading with us to stop and let him die. Every time you touched him he shrieked in pain from the pneumonia. I had to get an IV in him. I was sickened by the whole thing."

"Is it right to have 15 people in white coats tear open a patient's curtain, tell him to undress and do all sorts of dehumanizing things?" Harris asks. "Is it right to tell someone he's dying of cancer, with everyone standing around taking notes? As a medical student you see things you don't necessarily like. Suddenly you don this white coat and you see the same things and you're caught in between. You don't know whether you should join the club and start treating patients this way—whether it's right or wrong. If you back away you're told you aren't being aggressive. To be aggressive—to be willing to try any and every procedure—is the ultimate compliment."

These types of emotional dilemmas may be verbally suppressed by most students, but they surface in many other ways, such as depression, insomnia, loss of appetite, and anxiety, Weinstein says.

"Feeling bad about some things is normal, but there's no provision throughout medical school to deal with those feelings. Students are expected to treat the remarkable in a casual way. It's okay to feel anxious about an exam, but not about illness or death," Finkelstein adds.

To work these emotions out, students say, they have to go to outside resources such as friends and family. Up to one-fourth of each class seeks professional help at some point during medical school, Weinstein says. Within the school, there is little help.

"I have been in a number of traumatic situations. I have told young people and old people they have a disease from which they'll probably die. I've gone through the grieving process with hundreds of people. Yet I can think of only two times in almost four years that someone has asked me how I feel," Rubenstone says.

"I've asked other students and doctors who I know have to go tell someone they're going to die, for example, how they are. They always reply they're just fine, when they're obviously not fine. But if you ever wince in any way, if you come out of a patient's room and say it was heavy, the response is that you'd better get used to it.

"I don't want to get used to it. I want to be able to deal with it effectively. If you shut down your feelings, that's it. But that is what is demanded in medicine. It's an occupational hazard. This profession promotes, sustains, and supports shutting down your feelings, and that leads to impairment," she concludes.

Some efforts are being made to help students deal with the emotional side of being a physician. On a national scale, the Association of American Medical Colleges is conducting a three-year study on medical education. Preliminary reports, and regional hearings and symposia held by medical educators in response to the study, have discussed ways that medical education could be humanized.

At Stanford, a Committee on Well-being for Medical Students and Housestaff (CWBMS) was established in 1978 to address some of the socioemotional aspects of medical education and training. The goal, Weinstein says, is to positively influence the learning climate.

To help students with the massive amount of resource information on medical school topics, such as clerkships, internships, and national boards, a room called Broca's Area was established. All such information is available there.

Students have formed support groups that meet once a month. The meetings are "intense," students say, giving them a chance to discuss their feelings about what they're experiencing. Unfortunately, only about 45 out of about 340 students particpate.

In response to a need established by the CWBMS, a course titled "The Human Costs of Medical Education" was offered for the first time in 1982. It was designed to let students know they are not the only ones experiencing rough times, it's all right to feel what they may be feeling, what they may go through farther along in their training, and ways to cope with potential problems, Weinstein describes. Despite overwhelming effort and enthusiasm from faculty and community physicians, the course was cancelled during 1983 because only a few students came.

Weinstein, who headed up the faculty for the course, speculated that it failed because many students may not admit the need to attend such a course. "You have to feel okay about not feeling okay to find a place to go for help," Rubenstone says. Others, Weinstein continues, may not have wanted to spend what may have been their only free afternoon in yet another course. Other faculty say the course simply "got the shaft" by the curriculum committee because of the time slot it gave for the course to be held.

"The faculty as a whole has just not committed itself to dealing with the emotional side of medical education," Weinstein says.

And while they sympathetically listen to concerns with which students find themselves struggling, their response often begins with "When I was in medical school. . .," followed by a fond recollection of what at the time was a horror situation.

This attitude may be due in part to the fact that many physicians view the socialization process as somewhat of a hazing. The underlying thought seems to be if they could get through it and survive, so can today's students.

But is this the best way to experience medical education? Should students be taught to deny their feelings and be "tough"? The mere fact that physicians are now publically vocalizing their doubts about the process, which has never happened before, is a big step forward, says Dr. John Steward, associate dean of student affairs.

"Figuring out what to do to change the situation is not nearly as difficult as understanding the problem completely,"Finkelstein adds.

"If you learn to deal with your emotions and take care of yourself," McGee sums up, " you have a lot more to give to your patients and other people. And that is what being a doctor is all about."

STUDY ON EFFECTS OF SPACE TRAVEL SEEKS VOLUNTEERS

STANFORD—

Healthy men and women aged 30 to 50 are needed to participate in a study relating to space travel and blood pressure regulation in Stanford's department of endocrinology.

According to postdoctoral fellow Michael Ash, astronauts, upon returning to the earth's gravity after a period of weightlessness, may experience a fall in blood pressure when they stand upright.

"We are conducting studies in which volunteers sit in a warm pool, followed by a day of bed rest, to simulate the effect of weightlessness," he said. When participants arise, researchers will monitor pulse, blood pressure and blood chemistry, while testing ways to anticipate and prevent low blood pressure.

Volunteers will spend 48 hours in the study, conducted at Stanford University Hospital and affiliated facilities. They will receive, free of charge, a complete physical examination and laboratory test screenings.

Subjects are needed beginning March 21. For further information or to volunteer, call (415) 497-6675 between 8:30 a.m. and 5 p.m.

CULTURAL DIVERSITY: A MEDICAL WORKSHOP

STANFORD—

A multicultural health care workshop will be presented Saturday, March 26, by Stanford's division of family medicine and the South Bay Area Health Education Center (AHEC).

The workshop, developed by medical anthropologist and lecturer Elois Ann Berlin, Ph.D., is designed to enhance the skills of primary health care providers in the delivery of culturally sensitive health care.

The morning session will focus on the ways in which the health beliefs and practices of Southeast Asian refugees are relevant to health care delivery. The session will be followed by a catered Vietnamese luncheon.

In the afternoon, discussion will center around the influence of the Hispanic population's health behavior and belief systems on health care. The workshop, which will run from 8:30 a.m. till 5:30 p.m. in room 204, CERAS Hall, main campus, concludes with a Fiesta and live Latin music.

The workshop is an extension of the multicultural clinical teaching program initiated in the fall of 1982. It will accent an appreciation of the refugee and migrant experience, the transition to U.S. lifestyle, and the ways in which minorities are perceived.

Faculty include Dr. William Fowkes, Jr., chief and associate professor in family medicine; Dr. Thuan Duong, a resident at the San Jose Health Center; Virginia Fowkes, F.N.P., M.H.S., director of the Primary Care Associate Program; Berlin; Dr. Count Gibson, professor and chairman of the Department of Family, Community, and Preventive Medicine; Marita Grudzen, preceptorship coordinator in family medicine; Dr. Carlos Inocencio, a resident at the San Jose Health Center; and Dr. Gene Levitz, community physician.

Also Leona McGann, M.S.W., M.P.H., assistant professor in family medicine; Dr. John Radebaugh, clinical associate professor in family medicine; Dr. Eleanor Segal, lecturer in family medicine; Ruth Stark, F.N.P., M.H.S., director of the Women's Health Care Training Project; and Esperanza Garcia Walters, R.N., M.P.H., director of the South Bay AHEC. The musicians and caterers will also share their experiences.

The workshop is approved for continuing medical education credit through Stanford's office of postgraduate medical education. A registration fee includes educational materials and lunch.

Pre-registration is required. For information and to register, call (415) 497-7284.

COMMUNITY INVITED TO HEAR GUEST LECTURE AT MEDICAL SCHOOL

STANFORD—

Dr. Paul Leitman, director of the division of clinical pharmacology at Johns Hopkins University, will present the fifth Pfizer Lecture in Clinical Pharmacology Monday, March 21, at the School of Medicine.

In his lecture, entitled "Aminoglycoside Nephrotoxicity—Clinical and Biochemical Aspects," Leitman will summarize his research findings, which have both immediate and future implications in the use of aminoglycoside agents.

Leitman, who has both M.D. and Ph.D. degrees, holds the Burroughs Wellcome Chair in Clinical Pharmacology at Johns Hopkins. He is a leading authority in the area of aminoglycoside nephrotoxicity, a significant complication of therapy in many patients requiring these important antimicrobial agents.

Leitman and his colleagues have performed careful clinical studies examining the incidence of this complication and comparing the incidence with various aminoglycosides and combinations of antimicrobial agents. They have identified a number of clinical and laboratory variables which are useful in predicting the likelihood of aminoglycoside toxicity in the clinical setting.

At the biochemical level, Leitman and his colleagues have studied some of the biochemical changes induced in kidney cells by the aminoglycoside antibiotics which may be important in mediating their nephrotoxic effect.

The Pfizer Lectureship, started in 1978, is sponsored by Stanford's division of clinical pharmacology, and funded by Pfizer Pharmaceutical, Pfizer Inc. of New York City. Previous speakers have included Drs. Robert Lefkowitz, Ferid Murad, Daniel Nebert, and Peter Goldman.

This year's lecture, open to members of the medical community and the public, is jointly sponsored by the divisions of clinical pharmacology and nephrology. It will begin at 4:30 p.m. in room M114 of the Medical Center.

NEONATAL NURSERIES PAVE THE ROAD TO NORMAL LIFE

STANFORD—

Dr. David Stevenson presented a picture of a healthy, smiling five-year-old in bobby socks and pig tails as a symbol of the major contribution of intensive care units to premature infants in the past 25 years.

"Our major contribution really is in the survival of normal people," said Stevenson, assistant professor of pediatrics and associate director of Stanford University Hospital's intensive care nursery.

Just as important as raising the survival rate of infants born too soon is raising the quality of life for those infants saved, the physician said in a public lecture at the Stanford Medical Center Wednesday evening.

"If we stopped intensive care (for premature infants) right now, there would be a lot of deaths," he said. "But there would also be a great increase in the number of people surviving who would be severely injured."

The pig-tailed child in the slide on the screen was "Jamie," one of Stevenson's tiny patients five years ago. Born three months prematurely to a teen-age mother, Jamie weighed only 1 1/2 pounds.

When physicians performed surgery a week after her birth to remove dead and dying portions of her intestine, Jamie's bloated abdomen was scarcely wider than three of the surgeon's fingers.

The surgery was risky. The infant girl faced a 60-70 percent chance of dying and, even with successful surgery, would need months of hospitalization, round-the-clock care, and intravenous feeding. Stunted growth and malnutrition were possible if the salvaged intestine was unable to absorb food adequately.

But after consulting with surgeons and other members of the health care team, Jamie's mother consented to the surgery. Five years and $100,000 later, Jamie shows no signs of illness, Stevenson said. The cost of care for her first months of life were shared by family, the hospital, and, indirectly, the public, through increased insurance premiums.

Most patients in the intensive care nursery stay only a few days or weeks, with a much lower hospital bill, but Jamie's case demonstrates an extreme example of both the costs and therapeutic capability of such a nursery, said Stevenson.

A child Jamie's size born today has an 80-85 percent chance of surviving, with the help of intensive care, he said. "These children are virtually all normal," he added.

Modern obstetrical advances are major contributors to the improved survival rate, said the physician. Such advances include the development of drugs that halt premature labor long enough for other drugs to be administered that speed the maturation of fetal lungs. But the modern techniques have limits.

3-10-83

-more-

2-2-2

A critical time in the development of the fetus occurs around the fifth month after conception, when blood vessels develop close enough to the lungs' tiny air sacs to permit a healthy exchange of oxygen and carbon dioxide.

"If that has not happened (by the time the baby is born), the best of ventilators will be of no use," Stevenson said. "No matter how much gas you move in and out of someone's air saccules, no gas will be exchanged, and the child will die.

"Therefore, there are children who are born alive, who move spontaneously, who respond to stimulation, who cry out for help, who cry out for someone to attend to them, that you may not be able to avoid letting die."

In such dilemmas, "compassion wrestles with duty" in the intensive care nursery, Stevenson said. "We have a dual charge in medicine, not only to save lives, but to alleviate suffering."

"A physician should still act in concert with his oath, which is to avoid doing any harm—not to start technologies which are serseless in view of someone's developmental state, and to assist in any way possible to make sure that this person does not suffer."

Stevenson described a child whose intestine, somehow twisted and crushed while the child was in the uterus, is completely nonfunctional at birth. Although normal in every other way, that baby will die within two weeks, Stevenson said. Life-long intravenous feeding is not an option because it would result in infections and other complications that would also kill the child. "There is nothing anyone can do."

"If I can't save that baby's life, I'll do everthing in my power to make the baby as comfortable as possible for as long as that baby is alive," Stevenson said.

"We don't withdraw support, we simply shift the emphasis of support to something that is more appropriate for this person. That shift of emphasis would be to nurturance—to love, to warmth, to those things which any human being deserves to have."

Advances made in neonatal nurseries in the next decade will continue to improve the quality of life for survivors, Stevenson predicted. But the secret to preventing prematurity may come instead from improving education and nutrition of high risk mothers.

"There are other things which we may perfect as we work on drugs to stop labor and drugs to mature the baby's lungs functionally. But those drugs are not without risk."

"I would say that prevention (of prematurity) is going to come through other means beside pharmacological means, ultimaely," he said.

Stevenson spoke at the fourth in a series of "Progress in Medicine" lectures, held on subsequent Wednesday evenings this season to acquaint community members with the technical and ethical issues encountered in the intensive care unit.

The March 16 session will feature a panel discussion of health care professionals addressing the issue "Who suffers more—the health care team or the family?", while the last lecture on March 23 will be given by Ernie Young, the Medical Center chaplain, on "Ethical and Emotional Issues in the care of the dying patient and family."

Both lectures will begin at 7:30 p.m. in the Sherman Fairchild Auditorium at the Medical Center.

ASSOCIATION PROPOSED TO LICENSE BIOTECHNOLOGICAL PATENTS

STANFORD—

Companies would be able to "one-stop-shop" for biotechnological patents at U.S. universities if a concept unveiled at an industry association meeting is adopted.

The proposal calls for creating a nonprofit corporation—tentatively called University Licensing Association for Biotechnology (ULAB)—which would market certain biotechnology tools patented by participating universities.

The institutions would share the licensing revenues based on the volume of their patents used by industrial customers.

The proposal, based on a preliminary feasibility study, was presented in San Diego March 3 at the meeting of the Industrial Biotechnology Association (IBA) by Roger Ditzel, director of patent, trademark and copyright matters for the University of California system, and Niels Reimers, director of Stanford's office of technology licensing.

IBA is a high technology industry group. Most of its approximately 25 members are among the 73 firms which have licensed Stanford and UC's basic gene cloning patent.

Stanford and UC's patent covering basic gene splicing techniques was issued in December 1980. The discoveries were made by Stanley N. Cohen, professor of genetics at Stanford; and Herbert W. Boyer, professor of biochemistry at UCSF.

"That patent, broadly covering gene cloning techniques, would not be affected by this potential association," said Reimers. "The technology handled by ULAB would be specific biological tools, rather than the entire gene cloning process.

A biotechnology tool is defined essentially as a technique used by a scientist in the making of genetically engineered microorganisms, which in turn make possible the production of industrial or consumer products.

March 10, 1983

-more-

It has been estimated that 200 patent applications for biotechnology tools have been filed by U.S. universities which might be potential members of ULAB.

"We are at a unique stage in the transition from academic discovery to industrial application, characterized by a relatively rapid path from a scientific finding to commercial development," said Reimers.

"And large numbers of patent applications are being filed and granted for what amount to the basic tools used by the scientist.

"There is great potential for significant and possibly unnecessary transaction costs when license rights to these patents are negotiated."

Ditzel continued, "It is conceivable a company would need a dozen licenses from a dozen universities for any particular genetically engineered product. Many biotechnology tools might be used only once in making the microorganism needed in a process."

Reimers and Ditzel contacted colleagues at other universities and in industry who were similarly concerned. With gift support of $3,000 each from seven companies, a study of the concept was conducted by Mark Edwards, a student at the Stanford Graduate School of Business.

"To better focus the concept, it was prepared in a business plan format," Ditzel added.

Reimers said the ULAB concept currently has received the support of many researchers and administrators at universities but has not been officially endorsed by any institution, including UC and Stanford.

Under the proposal, potential users would be able either to license patents individually, or they could secure blanket rights to all patents in ULAB's portfolio.

Edwards' plan hypothesized a fee of $25,000 per year or 1 percent of net sales—whichever is greater—to enable a company to secure blanket rights to all patents offered by the association. Projections of the business plan indicate that if ULAB were chartered by 10-12 businesses and/or universities, each contributing about $50,000 in start up money, total gross revenues through ULAB during the next five years might amount to about $12 million, Edwards said.

However, Ditzel emphasized that while any eventual plan might have different terms or even a different structure, such an association appears to offer some substantial benefits to a rapidly growing industry.

In presenting the concep, Reimers wrote:

"In university laboratories there has been a growing concern that desire for proprietary knowhow or rights may stifle the open communication of scientists, particularly between scientists who have involvement with different companies.

"The (ULAB) concept would seek to reduce this secrecy and/or delay of publication and competition by making all biotechnology tools available to all scientists.

"Selection of a tool would be made by the industry scientist based on what was the best process rather than simply the single process which might have been selected by his company's management."

Reimers said the ULAB concept has been under study for about a year.

Income to universities would be expected to be used for research and education, and researchers and administrators at each university would have to endorse ULAB before their university could join the association, Reimers suggested.

ULAB could be set up as an independent nonprofit association. Alternatively, a high technology company or existing association could administer ULAB's business, Ditzel said.

Currently, revenues from the Cohen-Boyer patent have brought in more than $2 million in license fees, although so far insulin has been the sole product to be marketed in significant commercial quantities from bioengineering techniques based on the Stanford-UC patent.

"We are looking ahead about a decade to see the most significant end product developments from the patent," said Reimers. "That is why the next five to seven years is the period we would expect to see the most activity from ULAB as research is continued at universities and industrial uses expanded."

Stanford currently is responding to the tentative rejection last year by the U.S. Patent Office of a second Stanford-UC bioengineering patent.

Reimers said that Stanford membership in a future ULAB-type association would not hinge on the outcome of the current patent application, particularly since the university owns a variety of patents not related to the one currently pending.

PERINATAL NURSING SYMPOSIUM

STANFORD—

"Advanced Perinatal Concepts: A Nursing Symposium" will be held March 23-25, in room 270, Tresidder Memorial Union, on the Stanford University campus.

Cosponsored by Nursing Educational Services and the Perinatal Nursing Region of Stanford University Hospital, this symposium is designed primarily for the perinatal nurse practicing in a tertiary level center. It is offered to broaden the nurse's understanding of high risk care.

Selected disease states, ethical and legislative issues will be discussed, as they pertain to maternal/fetal/neonatal management and outcomes. In addition, innovations in management and health team communications will be presented. Small group presentations in the afternoon will encourage in-depth examination of specific problems particular to each patient group.

Faculty will include many professionals from Stanford University Medical Center, as well as several guest participants.

For more specific information on the program, registration, fees, lodging (if necessary), educational objectives, continuing education credit, faculty, and specialty topics, call (415) 497-6366. Early registration is advised.

AGREEMENT ON HOSPITAL ACCESS AT LAST

STANFORD—

An extended policy governing access of community physicians to Stanford University Hospital's sophisticated equipment and specialty laboratories was approved Friday by the Board of Hospital Directors.

The policy establishes:

- a method of deciding how community physicians would be granted access to both present and future hospital specialty laboratories,
- a permanent hospital board committee to advise the directors on access issues, and to monitor the implementation of policies,
- a mechanism for appealing decisions, and
- representation of community and faculty physicians on access committees at the departmental and board levels.

The new policy was recommended by a committee headed by hospital board member Dean Morton after deliberations of 15 months. The committee was made up of board members, and included faculty and community physicians.

Morton termed the recommendations "a significant improvement" in the policies and procedures adopted by the hospital board in August 1981. The policies in question were the result of negotiations between the university and community physicians, which reversed an earlier hospital policy limiting future use of the specialty laboratories to full-time faculty only. That agreement set up a formula through which local doctors who then had access to the laboratories could be replaced by community specialists when they resigned or retired.

But access to other equipment, including future technologies, remained still an issue. In addition, community doctors applying for access to the specialty laboratories complained that some clinical service chiefs were not acting promptly on their applications.

In his report to the hospital board, Morton said all clinical services of the hospital now had functioning access committees in accordance with hospital policy.

"The Anesthesia access committee has acted to replace several physicians," Morton said. "Access to the Cardiac Catheterization and Angiographic Lab has been available and utilized by two community physicians for the past 11 months, and formal affiliation agreements were recently signed." In addition, the radiology service has granted access to two physicians.

Morton said access arrangements for community physicians were being discussed by the Radiology Service with respect to CT scanning and Ultrasound Laboratories.

Similarly, Morton added, a Neurology Service access committee was meeting to act on outstanding replacement positions for the Electromyography and Electroencephalography laboratories.

Lawrence G. Crowley, vice president for medical affairs, termed the agreement "a good compromise" that balances the desires of private practitioners against the needs of the Stanford Medical School to fulfill its role in patient care, teaching, and research.

3/7/83

-more-

"The policy," he said, "guarantees an opportunity and process for community physicians to make their case on access issues all the way to the hospital board, if necessary.

"It also assures the full-time faculty that access to the laboratories will be limited and that academic program quality will be recognized as of great importance along with the provision of optimal patient care."

Crowley noted the agreement recognizes that technology, financing mechanisms, utilization rates and staffing needs constantly change.

"The hospital board," he said, "with the advice of its access committee, will continuously review these changing circumstances and adjust its policies from time to time."

He said the agreement "places the access issue with other important policy issues within the jurisdiction of the hospital board where it belongs."

"It's the board," he said, "that has the authority and responsibility for the successful operation of the hospital."

Committee members at the Friday board meeting gave qualified support for the committee recommendations.

"The important aspect is that for the first time we have a document for dealing with future issues equitably," said Dr. Walter Arons, a community physician.

"There are faculty physicians and local doctors who are not particularly happy with the concept of limited access developed by the board in 1981," said Dr. Ronald Castellino, associate professor of radiology.

"But we all felt it was essential for the good of this institution to come up with the best we could do."

The document, Castellino added, establishes procedures to implement the board's 1981 policy on limited access, and in that respect it represents a reasonable report.

Dr. R. Hewlett Lee of the Palo Alto Medical Foundation said very divergent philosophies had been thoroughly explored and after one and a half years of meetings a "consensus document" had been agreed upon by the community and faculty physicians and board members of the access committee.

Lee termed the new policy as "a foundation for solutions to the access problems."

"It's a consensus document," agreed Dr. Wilbur Mattison of the Menlo Medical Clinic. "It means there are still reservations and points of disagreement between the physicians on the committee. But we think it is a very reasonable and workable document that provides us with procedures to put into effect the 1981 board policy."

Last August the Palo Alto City Council became involved in the access issue when it gave conditional endorsement to Stanford University Hospital's modernization project. The Council reserved the right to rescind its endorsement if the Morton committee had not made what Council members deemed sufficient progress toward settling longstanding discussions about community physician access to the specialty laboratories.

Council endorsement is not required. However, the state and regional agencies which must approve all hospital construction projects, review local community support while assessing whether the requested improvements are needed in the local area.

The membership of the Morton committee included Drs. Ronald Castellino, Duncan Govan, Sharon Hunt, R. Hewlett Lee, Wilbur Mattison, Richard Popp; and Linda Meier and Geraldine Steinberg, with Dr. Walter Arons, Crowley, and Stanford University President Donald Kennedy serving as ex officio members.

STANFORD—

Dr. Aaron Klug, winner of the 1982 Nobel Prize for Chemistry, will deliver two lectures at Stanford University School of Medicine Center March 14 and 16.

Klug, of the British Medical Research Council Laboratory of Molecular Biology in Chemistry, is the 38th invited speaker since the Course of Lane Medical Lectures was established in 1896.

The talks, now held every once every two years, were established to draw outstanding scientists from around the world to speak to members of the medical profession, students, teachers, and research workers in medicine and allied sciences.

The series was founded by Dr. Levi Cooper Lane, and held at Cooper Medical College in San Francisco until that institution became Stanford's medical school.

Klug, who received his Ph.D. from Cambridge University in England in 1952 after studying at the University of Cape Town in his native South Africa, was cited by the Nobel Prize committee primarily for his contributions toward understanding the structure and complexes of proteins and nucleic acids. He was also cited for his development of crystallographic electron microscopy.

In addition to his position at the molecular biology lab, Klug serves as joint head of the Division of Structural Studies at Cambridge. He is the author of numerous publications in his field.

On March 14, Klug's talk will be "Structural Analysis of Macromolecular Assemblies by Electron Microscopy and Image Reconstruction." On March 16, he will discuss "From Viruses to Chromatin." Both lectures are to be held from 5 to 6:15 p.m. in Sherman Fairchild Auditorium.

STANFORD PHYSICIANS TELL PREMEDS THERE'S MORE TO LIFE THAN SCIENCE

STANFORD—

The common belief among aspiring physicians is that in order to be accepted to medical school they have to spend their entire premedical education taking science classes, doing research, and working in hospitals and laboratories.

That's not so, say many accomplished physicians. And that's the message they plan to relay to undergraduate students during a panel discussion, "Reflections on Medicine: Education, Lifestyle, and Diversity."

The panel, scheduled for 7 to 9 p.m., May 9, in Stanford University Medical School's Sherman Fairchild Auditorium, will discuss the pros and cons of choosing medicine as a career. Panel members are Dr. Harvey Weinstien, clinical assistant professor of psychiatry; Dr. Elizabeth Short, associate dean of student affairs; Dr. Sarah Donaldson, associate professor of radiology; Dr. Bruce Parker, associate professor of clinical radiology; and Drs. Roger Peeks and Tom Fiene, both in private practice. Medical School Dean Dominick Purpura will chair the panel.

Medical students and housestaff will be at a reception following the panel. Together with the panel members, they will be available to talk with students about the various routes they took before entering medical school.

"Students should choose a major that interests them," said Audrey Bernfield, coordinator of departmental student services for humanities and sciences. "They should worry about medical school when they get to it. They shouldn't gear their whole life around it."

Stanford's School of Humanties and Science, Academic Information Center, and Medical School are co-sponsoring the panel. It is a kick off for the Majors Event, May 10, in the Inner Quad, during which undergraduate students will have the opportunity to learn about all majors from faculty, graduate students, and alumni.

STANFORD— **PSYCHIATRISTS TO STUDY NARCOLEPSY IN DOGS UNDER NIH GRANT**

A major study into the mechanisms and causes of narcolepsy has been launched by Stanford University psychiatrists under a grant from the National Institutes of Health.

Narcolepsy is a neurological condition that causes irresistible sleep attacks in its victims. Originally, the disease was thought to be rare, but research has shown it to be more widespread, now afflicting about 250,000 Americans.

The disorder is characterized by excessive daytime sleepiness, cataplexy (abrupt attacks of muscular weakness), and sudden attacks of or desire for sleep. REM (rapid eye movement) sleep, at uncontrollable intervals, results.

Under a $100,000 a year grant for the next three years, researchers headed by Dr. William Dement will study narcoleptic dogs that manifest the same symptoms as in the human condition. The research is expected to provide important clues to causes and treatments.

Dement, professor of psychiatry and behavioral sciences, is director of Stanford's Sleep Disorders Center and a recognized leader in the field.

"People have suffered from narcolepsy for hundreds, probably thousands of years," he said. "Only in the last few years has it become widely recognized as a distinct medical disorder, and the object of major research."

The study will include new technical advances such as development of a system which can take long-term neurophysiological recordings in unrestrained dogs.

With the only population of narcoleptic dogs in the world, investigators contend, Stanford is in a unique position to conduct comprehensive research on neurochemical, anatomical, and physiological aspects of the disorder.

-more-

4-27-83

"Studies in humans are difficult, expensive, and necessarily limited in scope," said Dr. Theodore Baker, the research associate directing the new project.

According to Dement, none of the drugs thus far used to treat the symptoms of narcolepsy have offered a cure. They are often habit-forming, provide only temporary relief, and can be accompanied by detrimental side effects.

A severe, debilitating, chronic condition, narcolepsy often leads to visual and memory problems, poor driving, home and work problems, headaches, nightmares, and the risk of drowning or other fatal accidents.

"Constant suffering is the companion to those with narcolepsy," said Dement.

In previous studies with dogs, Dement and his colleagues found a strong genetic basis for narcolepsy, and uncovered a variety of scientific facts relating to the neurochemical imbalance which causes it. The present study aims to expand research already begun in Stanford laboratories.

"We hope that this canine research will lead to an understanding of the basic defect underlying narcolepsy. This could lead in turn to more effective treatments aimed at correcting the defect," Baker said.

Investigators, besides Dement and Baker, include Drs. Jack Barchas, professor of psychiatry and director of the Laboratory of Behavioral Neurochemistry; Roland Ciaranello, associate professor of psychiatry and director of the Laboratory of Developmental Neurochemistry; Craig Heller, associate professor of biological sciences; and James Meindl, professor of electrical engineering, and director of both Stanford Electronics Laboratories and the Center for Integrated Systems.

CONGRESS MUST SUPPORT BASIC TOOLS OF RESEARCH, SCIENTIST URGES

STANFORD—

Technological advances to improve the practice of medicine are significantly slowed by a lack of modern instrumentation facilities and to the detriment of the public that could benefit, a Stanford University scientist told a Congressional subcommittee Friday (April 29).

In testimony prepared for delivery before the Labor-HHS-Education appropriations subcommittee in Washington, D.C., Dr. Oleg Jardetzky urged Congress to increase funding by a recommended $20 million per year in the budget of the National Institutes of Health for instrumentation programs.

Presently, the principal programs for instrumentation funding are in the Division of Research Resources of the NIH, with budgets of $27.7 million for fiscal 1983.

Jardetzky, a professor of pharmacology, directs the Stanford Nuclear Magnetic Resonance Laboratory. He testified before the subcommittee as president of the Association for Advanced Technology, a group composed of directors of publicly-supported laboratories that are national or regional centers of research.

The recommendation was part of a 1982 NIH report which acknowledged that the quality, quantity and development of scientific instruments available for research in the United States had rapidly declined. This threatened to diminish the leading position of the United States in research, the report concluded.

The report called for increased funding of research equipment and instrumentation "to replenish and maintain the adequacy of the biomedical research community's needs" for the next five years.

Because sophisticated instrumentation such as million-volt electron microscopes, nuclear magnetic resonance, synchrotrons, and computers programmed for graphics and artificial intelligence, for example, are costly—often running in the six figures—the report urged that advanced instruments be used through shared facilities.

However, the Congress has increased the budget for this purpose only by $12.5 million for fiscal 1983.

"This sum is far below the estimated need," Jardetzky told the subcommittee. "It is not adequate to meet the new needs generated by recent technological developments."

Among examples, Jardetzky cited his own field, nuclear magnetic resonance (NMR). This is a technique that can provide a glimpse inside the human body without scalpel, needle or hazardous x-rays, and more complete than anything obtained with CT scans.

Today 14 instrument manufacturers are developing NMR imaging equipment, Jardetzky noted, but funding sources for such instruments in universities and hospitals remain ill-defined.

"The hope is that the costs of instrumentation—of the order of $2 million per unit—will be defrayed by income from patient care does not take into account that for the immediate future at least the technique must be used on an experimental basis and applications must be closely tied in with further development," he said.

The combination of NMR techniques has enormous potential as a tool for diagnosis and for evaluating therapy results in a number of diseases, Jardetzky said. Yet manufacturers are concentrating on simpler, more immediately marketable NMR imaging equipment while needed funding for more sophisticated developments cannot be identified.

Jardetzky argued that funding of shared facilities by the NIH since 1962 has demonstrated the validity of this concept.

"Ultrasophisticated instruments, the latest state-of-the-art methods, and expert support personnel in installations open to many users help life scientists in their efforts to decipher fundamental biological processes or combat human illness," he said.

Stanford has five national facilities: the Stanford Nuclear Magnetic Resonance Laboratory, Stanford University Medical Experimental Computer for Artificial Intelligence in Medicine (SUMEX-AIM), Stanford Synchrotron Research Laboratory, Mass Spectroscopy Laboratory, and Stanford Electronics Laboratory (SEL).

BONE MARROW TRANSPLANT DONOR IDENTIFICATION PROGRAM SOUGHT

STANFORD—

An effort to help identify potential bone marrow transplant donors was announced Tuesday by Stanford Medical School Blood Bank in the wake of an appeal by two Long Island businessmen to save a leukemia victim's life.

F. Carl Grumet, associate medical director of the blood center, said informational letters would be sent, within the next several weeks, to a select group of donors who have undergone extensive blood typing at Stanford and elsewhere.

Grumet spoke at a news conference with David Kolatch and David Welner, who came from New York to Stanford in search of a blood donor for a friend, whose only chance of survival from leukemia is a bone marrow transplant.

Edgar Frenkel, 34, a psychiatrist, has chronic mylogenous leukemia. His doctors estimate that he probably has only months to live without the transplant, Kolatch said.

A precise match of blood type is required to ensure a successful marrow transplant, and only about one person in a million in the general population would qualify, said Grumet.

Stanford is not unique but is one of only a few centers nationally where precise blood typing of characteristics called HLA antigens have been done on about 1,000 blood donors.

Grumet said a cursory check has not yet disclosed any donors where each of six potential factors match, but he will send letters informing all of his donors who have been typed of the need for Frenkel, and the potential to donate marrow for other leukemia sufferers.

Grumet said he ruled out attempting to identify and contact a specific donor for Frenkel from among his lists, "because it is unfair to ask people who have agreed to donate blood for purpose A to have their name added to a list for purpose B."

Stanford runs HLA tests on a group of volunteers who agree to donate blood platelets on a frequent basis for patients who need a tailor-made match of blood types.

"These donors are really special people who are already giving quite a bit. We do not want to put them under undo pressure," Grumet said.

April 27, 1983

-more-

Ironically, Grumet said that the closest match he has found from a cursory screening is himself, with four out of six of the HLA factors matching. Two persons with five out of six factors matching have been found in other searches around the country, Kolatch said, but most transplant centers insist on a six out of six match before they will operate.

Until very recently, Grumet said, bone marrow transplants would not be performed on matches of donors from outside the patient's family. While only a few cases currently come to the attention of blood banks annually, Grumet said medical progress will increase the need for unrelated bone marrow donors in the future.

Grumet, as well as Kolatch and Welner, are hopeful that the current effort will initiate, in collaboration with other blood and transplantation centers, a national registry of potential volunteer bone marrow donors.

Obtaining marrow from the donor causes temporary discomfort but involves essentially no risk for the donor, he added.

"We're hopeful that as we pursue this, we will be able to find a donor (for Frenkel). But even if we can't, we hope that what we do will be of lasting use to society," said Kolatch.

Finding a suitable donor for a bone marrow transplant outside a patient's immediate family is always difficult, because of the complicated tissue matching that must be done.

But Frenkel has several rare factors that decrease the chance for finding a perfect match to about one in several hundred thousand among the people who have been HLA tested, Grumet said. (Although the odds in the world population are one in a million, Frenkel's rare traits occur slightly more frequently among Ashkenazic Jews—a group Frenkel's friends have targeted in New York in their publicity campaign to find HLA tested volunteers).

Frenkel's problem is compounded further by the fact that, while many people know whether they have A or B type blood, few have been tested for HLA type. The sophisticated typing procedure costs several hundred dollars per person, and is performed by only a few dozen laboratories around the country.

Because of the expense of the extended HLA typing procedure, the "Emergency Support Fund," set up by Frenkel's friends, has asked that only persons who have been previously HLA tissue typed contact them. Inquiries from potential donors can be addressed to Bone Marrow Transplant Search Center,P.O. Box 600, Cedarhurst, New York, 11516.

Kolatch said an offer of $25,000 made in New York earlier was still in effect for the donor.

HLA stands for "Human Leukocyte Antigens"—proteins that appear on the membrane of white blood cells. While every human being can be divided into the four familiar A, B, AB, and O blood groups according to their red cell type, the number of distinct HLA blood types possible runs into the thousands.

In addition to its use in research, HLA typing is most often performed to identify uniquely compatible donors who can provide custom-tailored blood products, such as platelets, for patients whose blood disease prevents them from being helped by blood transfusions from random donors.

NEW NATIONAL ACADEMY OF SCIENCE MEMBERS

STANFORD—

Two members of the Stanford University School of Medicine faculty have been elected to the National Academy of Sciences (NAS), the academy announced Tuesday (April 26).

They are Ronald W. Davis, professor of biochemistry, and Dominick P. Purpura, a noted neuroscientist and dean of the School of Medicine.

Davis' research has dealt with gene manipulation, and he is a widely-recognized electron microscopist. While at the California Institute of Technology, he developed the electron microscope heteroduplex method of investigating the sequence of nucleic acids, and analysis which has had significant uses in mapping sequences of DNA molecules.

He came to Stanford in 1972 where his research has been on yeast genetics and gene manipulation.

Purpura became dean in 1982, coming from the Albert Einstein College of Medicine. He is the holder of the Carol and Elizabeth Naumann endowed chair as well as professor in the departments of Neurobiology and Neurology. He is noted for research in human cortical development using basic data and techniques of neuroscience.

He has been among the first to observe that the brains of children, who are mentally retarded with no known chromosomal aberrations, had structural abnormalities in their nerve cells.

Their election brings to 80 the number of Stanford faculty elected to the prestigious NAS membership. Sixteen of these are in the School of Medicine.

STANFORD SYMPOSIUM TO EXPLORE PROMISE OF "NEW GENETICS"

Science writers: You are invited to attend a day-long meeting on "Perspectives in Molecular and Genetic Medicine," May 13. The meeting, one in a series, will explore the status of molecular medicine advances and their application to specific areas of genetics and human disease. Copies of the program are are available on request if not included with story.

STANFORD—

The promise of "new genetics" now shaking the very foundations of modern medicine will be the topic of a day-long symposium Friday, May 13 at Stanford University School of Medicine.

The symposium, which will begin at 8:15 a.m. in Sherman Fairchild Auditorium, is part of a series of meetings at Stanford on the subject of molecular and genetic medicine.

According to Dean Dominick P. Purpura, Stanford is now formalizing a broadly based program in molecular and genetic medicine involving faculty from both the basic and clinical sciences.

"The purpose of the academic program," Purpura said, "is to provide the scientific and intellectual framework necessary to speed the pace of anticipated research advances and their translation into revolutionary methods of diagnosis and therapy of human disease."

Collectively, the techniques of molecular genetics are known as genetic engineering—a term that captures the skill and precision with which human DNA can be inserted into the genetic machinery of bacterial and yeast cells and made to function.

Bacteria with human gene transplants can churn out vast quantities of man's own body chemicals expected to be used to treat disease. By peering into human genes, scientists can now predict with uncanny accuracy which individuals are likely to be afflicted with *what* diseases over the entire course of their lives. And attempts to cure patients of hereditary defects are contemplated in the not far-distant future.

"The excitement and promise of the 'new genetics' both as a research tool and as applied to the study and treatment of diseases, have deep roots at Stanford," Purpura noted.

Among the speakers will be leaders in molecular genetics from the Carnegie Institution in Washington, Columbia, Harvard, Stanford, University of California in San Francisco, and University of Texas.

Topics will include "Viruses, genes and cancer," "Oncogenes among antibody genes and implications for human cancer," "Transposable elements and their use as genetic tools," "Lipoprotein receptors: genetic defense against heart attacks," and "Steps toward a molecular grammar of learning."

The symposium is open to invited guests and faculty, students, fellows, interns, residents, and staff.

Copies of the program can be obtained from the Office of Public Events, Stanford University School of Medicine, 800 Welch Road, Suite 221, (415) 497-6389.

1983 SCHULTZ LECTURE ON HEPATITIS-B SET FOR MAY 9

STANFORD—

The sixth Edwin W. Schultz Memorial Lecture, given this year by Dr. Jesse Summers of the Philadelphia Institute for Cancer Research, will take place Monday, May 9, at Stanford Medical Center.

Summers, a senior member of the Institute, will discuss "Molecular Studies on the Replication and Pathogenesis of Hepatitis B-Like Viruses Using Animal Models" at 5:15 p.m., in Fairchild Auditorium. The public is invited, and there is no admission charge.

The noted virologist is researching viral replication and pathogenesis of hepatitis B and related animal viruses. His research offers a chance to study diseases in animals resembling those caused by the hepatitis B virus in humans, including liver infections and liver cancers.

Summers received his graduate training in microbiology at the University of Texas at Austin and later studied at the Salk Institute in San Diego, before joing the Institute for Cancer Research.

The Schultz lectureship honors Dr. Edwin W. Schultz who served as chairman of medical microbiology for 33 years. The memorial lectureship was established at his death in 1971 by his family and friends. The lecture is hosted by the department's graduate students.

For further information, call Shayne Frankel at (415) 497-9202.

EMERITUS FACULTY MEMBER RECEIVES HONOR

STANFORD—

Dr. Maurice Grossman, clinical professor emeritus of psychiatry and behavioral sciences, has received the Outstanding Achievement Award for 1983 of the Northern California Psychiatric Society (NCPS).

The award honors members of NCPS, a branch of the American Psychiatric Association (APA), in recognition of exceptional contributions to psychiatry and the greater community.

The presentation was made at an Asilomar ceremony earlier this month by Dr. Thomas Gonda, professor and chairman of Stanford's department of psychiatry, who commented, "In everything Dr. Grossman has done in medicine, he has held the interests of patients, both his and those of his colleagues, as coming first."

An internationally recognized authority on problems of confidentiality, Grossman played an increasingly important role throughout the 1960s in legislation related to psychiatry, beginning with his presidency of NCPS in 1960. He has continued this activity in various capacities in organized medicine.

Specifically, Grossman has worked with insurance industries, the California Medical Association, and the American Medical Association on issues of protection for patient confidentiality.

Earlier, he developed innovative occupational, hospital-wide treatment programs for the chronic psychiatric patients of Veterans Administration hospitals. These programs were adopted throughout the VA system over the course of 15 years.

An offshoot of this work was Grossman's recognition of the psychodynamics of chronicity, and the application of this knowledge in rehabilitation to problems of chronic illness in general. Grossman's activity on the federal and European scene began with this field of medicine.

Grossman received his M.D. in Philadelphia, the city of his birth, from the Jefferson School of Medicine in 1931.

Already trained in surgical pathology and experienced in general practice, he took psychiatric training at the VA Hospital in Palo Alto.

During the 1950s Grossman held simultaneous appointments on the clinical faculties of two medical schools: at the University of California, San Francisco, in psychiatry; and at Stanford in physical therapy. At that time he taught psychological medicine to physical therapy students.

In 1958 Grossman joined Stanford's department of psychiatry. He is a Life Fellow of the APA, and was one of the organizers and first moderator of what is now the California Psychiatric Association.

Listed in *Who's Who in the West*, Grossman is the author of numerous articles and is currently preparing a summation of trends in American psychiatry, at the request of his colleagues in France, that encompasses developments in the 1900s which explain the situation today.

Heart Health Fair Set for May 20

STANFORD—

The first annual Heart Health Fair, sponsored by Stanford University Hospital (SUH), will take place Friday, May 20, at the Stanford Shopping Center from 11 a.m. to 7 p.m. The public is invited, and the event is free of charge.

The Fair, intended to promote community awareness of available resources for the prevention of cardiovascular disease, is coordinated by the cardiac patient teaching committee of the department of nursing service at SUH.

Registered nurses, dietitians, and other health professionals will staff approximately 10 booths, according to Maureen Kennedy, R.N., nursing educational coordinator. These people will offer information on topics including the anatomy and physiology of the heart, cardiac risk factors, and yoga and aerobic exercise. Blood pressure checks will be offered, and those wishing to donate blood will be able to make arrangements with representatives from the Stanford Blood Bank.

For further information, call Kennedy at (415) 497-6706.

MEDICAL ANTHROPOLOGIST TEACHES M.D.S HOW TO MORE EFFECTIVELY TREAT PATIENTS

STANFORD—

A young Vietnamese woman gives birth to a healthy baby. Her physician gives her post-delivery instructions, to which she smiles and nods in agreement. But the nurses note on her records that she resists all medication and baths.

The physician is concerned about her apparent noncompliance. But in reality, the mother, in accordance with her cultural beliefs, is simply trying to gain back the heat she lost during childbirth. She cannot understand why the nurses want her to take showers, which may chill her, and give her cold water with which to take her medication.

Cultural differences in health beliefs and practices such as these often interfere with the effectiveness of treatments, said Dr. Elois Ann Berlin, a medical anthropologist. This is especially important in areas in which large numbers of immigrants settle.

For example, she said, a federally-funded study of California's population growth during the past decade reports a total increase of 10 percent. While the white population increased only .7 percent, according to the *West Bay Area Health Systems Agency* report, the hispanic population increased 33.3 percent and the Asian population increased 41.1 percent.

Berlin, who is working through the South Bay Area Health Education Center at Stanford University School of Medicine, has developed a multi-cultural clinical teaching program for health care providers. With her guidelines, which she teaches to residents at the Family Practice Residency Program, Stanford medical students as a guest lecturer in internal medicine, pediatrics, and family medicine, and community physicians at special workshops, they can more effectively treat members of the various cultures that have settled in the Bay Area.

"The fundamental concept to teach physicians is attitude," Berlin said. "They have to be receptive to their patients, and must realize the patients do have an explanation of the illness they're experiencing and that it may not fit in the biomedical model."

The key to more effective treatment, she said, is to incorporate the patient's treatment according to cultural beliefs with biomedical treatments.

-more-

Many cultures, including hispanic and Asian that are the Bay Area's most prevalent, derive their health beliefs from humoral pathology, an ancient theory that good health is the result of a balance of the body's four humors: blood, phlegm, yellow bile, and black bile.

There must also be a balance between hot and cold substances in the body, the theory prescribes. Chinese traditional medicine, Yin/yang, which specifically influences Asian health beliefs, prescribes the same concept. So in the case of the new mother, she was not resisting her physician's treatment, but merely trying to restore the balance that had been disrupted by childbirth.

Physicians should let patients say what they are experiencing, rather than asking them if they have specific symptoms, Berlin said. In many cultures it is considered impolite to disagree, she explained, so they would agree with every symptom their physician mentioned.

After listening to patients' perceptions of their ailment, physicians should try to explain the biomedical reasons for the ailment. This can be especially difficult, Berlin added, because many cultures have differing perceptions of anatomy or pathology.

After acknowledging the similarities and differences of the perceptions, physicians should recommend and negotiate treatment. The mother's physician, for example, may have agreed to allow her to take sponge baths, or perhaps have told the nurses to give the mother warm water with which to take her medication.

Berlin has also accumulated information about the various cultures for physicians, which includes many idiosyncrasies that may indirectly affect treatments. For example, in Asian cultures the soul resides in the head. The common practice of patting a child on the head could startle the soul and cause it to run away, Berlin explained. In order to avoid this, she said, physicians should always ask permission to touch patients' heads during a clinical examination.

Among hispanics, on the other hand, blood is considered to be in limited supply, and is equated with strength and virility. Patients may resist blood tests for this reason, Berlin explained, and physicians must quell their concerns.

Berlin is making video tapes of role play between physicians and patients to supplement the written material. She hopes to disseminate both as a package to medical schools throughout the country.

"The combination of medicine and anthropology in making treatment of culturally-diverse populations more effective is rare," she said. "Our goal is to give physicians an awareness of the types of differences they may encounter, how to elicit those differences, and alternative ways to deal with them without antagonizing the patients or hampering the effectiveness of the treatment."

Volunteers Needed for Herpes Research

STANFORD—

Men and women suffering from herpes are needed to participate in a study being conducted by the division of infectious diseases at Stanford University Medical Center.

Persons with either type of herpes (HSV-I or HSV-II) are eligible to participate, but volunteers must experience outbreaks on the arms, legs or trunk, and *not* around the eyes, lower face or genitals, said Dr. Tony Cunningham, an investigator in the study being conducted by Dr. Thomas Merigan, head of the division.

When the volunteer has a recurrence, researchers will take two tiny, painless tissue samples from the affected area to test for the presence of certain types of cells which fight off the virus. Cunningham said they hope the results of the study will help lead to the development of a treatment to prevent recurrences once the virus has been contracted.

Volunteers will be paid a fee for their participation.

For further information or to volunteer for the study, call Cunningham at (415) 497-5908 between 9 a.m. and 5 p.m.

—30—

Volunteers Needed for Sleep Research

The Sleep Disorders Research Center at Stanford University Medical Center is once again seeking volunteers to test the daytime alertness of persons taking sleep medication.

Sue Cohen, a research assistant, said about 25 volunteers are needed, and should be men or women aged 21 to 60 who are suffering from insomnia. They must be willing to take sleep medication during a 21-day period and spend 11 nights and six weekend days at the Sleep Center's lab in Palo Alto.

Three separate starting dates will be available through June, Cohen said.

Some volunteers will receive medication while others will get a placebo.

Participants will be electronically monitored in the lab at night and perform skill tests during the day to test alertness.

Volunteers will be paid $400. They will also receive two free medical exams and lab workups. Meals will be provided free during the live-in phase. Private rooms and amenities—including free movies—will be furnished.

For further information, contact Cohen at 325-4697.

NEW ASSOCIATE DEAN NAMED

STANFORD—

Dr. Roy H. Maffly, Stanford University professor of medicine (nephrology), has been appointed associate dean of student affairs at the Medical School.

Maffly succeeds Dr. Elizabeth M. Short, who is leaving Stanford to join the Association of American Medical Colleges in Washington, D.C.

In his new position, Maffly will be involved with the clinical education of Stanford's medical students. His responsibilities will include assigning students to clerkships and writing letters to support their applications for internships.

"I look forward to working with the students in a closer capacity," Maffly said. "I hope to continue teaching, which I feel will make me more effective as associate dean."

Maffly came to Stanford in 1961 as assistant professor of medicine. He was promoted to full professor in 1970. He has co-headed the nephrology division since 1971, and was acting chairman of the department of medicine from 1977-78. He is a staff physician and chief of the renal service at the Veterans Administration Hospital in Palo Alto.

Maffly also directs StanMed, the School's computer system for medical education.

Maffly is actively involved with student affairs. He is a member of the National Board of Medical Examiners Part II Medicine Test Committee. He has chaired Stanford Medical School's Minority Admissions Committee, Faculty Senate, and Committee on Courses and Curriculum. He has been director of admissions since 1981.

A new director of admissions has yet to be named.

Maffly has been often honored for his teaching. He has received the Henry J. Kaiser Award for excellence in teaching three times, the Henry J. Kaiser Award for outstanding and innovative contributions to medical education, the Arthur L. Bloomfield Award for excellence in teaching, the Walter J. Gores faculty achievement award for excellence in teaching, and the Award for Outstanding Teaching by the Medical School class of 1971.

STANFORD MEDICAL SCHOOL FACULTY, STUDENTS PRESENT MUSICAL PLAY

STANFORD—

Stanford Medical School faculty and members of the class of 1983 will present a musical play, *The Hypocritic Oaf,* at 8:30 p.m., April 29, in Dinkelspiel Auditorium on Stanford University's campus.

Produced by the Medical Alumni Association and directed by students Laura Esserman and Joe Sachs, the musical features songs written, composed, and performed by students and faculty.

The two-act play follows a medical student through his education and training, according to Esserman. "In the beginning, God created the medical student, and indoctrinated him to the culture, and he matured, and he differentiated, and he reached the top!," reads the story line. It includes the scores: "I Hope I Can Get In," "A Day In The Life Of Dr. Paul Berg Nobelovitch," "This National Bored Test," "My Heart Belongs To Shumway," "Leukemia Rag," "Matchmaker," and "I've Grown Accustomed To This Place."

Tickets will be sold at the medical student lounge from noon to 1 p.m. April 22, and are available at the Medical Alumni Association Office, 800 Welch Rd., Suite 221. Commemorative t-shirts are available as well. A complimentary happy hour will be held before the show, from 6:30 to 8 p.m. at the Stanford Faculty Club. For more information, call 497-6389, or 497-5064.

RESEARCH CENTERS OPPOSE ANIMAL BILL

STANFORD—

Proposed state legislation which would bar pound animals from medical research would be an enormous disservice to pet owners, the general public, as well as research, officials of two research-oriented California medical schools said Friday.

The protests against Senate Bill 883, scheduled for a hearing Tuesday by the Senate Judiciary Committee, came from Lawrence G. Crowley, vice president for medical affairs at Stanford University; Dominick Purpura, dean of the Stanford School of Medicine, and Julius Krevans, chancellor of the University of California, San Francisco.

The bill, sponsored by Senate Majority Leader David Roberti, R-Los Angeles, would prohibit the selling of unclaimed pound animals—which are routinely euthanized—to research institutions and would instead require that such organizations buy animals especially bred for research.

The bill would do nothing to improve the humane treatment of animals, "a concept we are genuinely committed to," said Purpura. However, he added, the measure would dramatically increase the cost of most biomedical research, eliminate some research, result in the death of thousands of additional dogs and cats annually, as well as make it more difficult in some cases for pet owners to reclaim their animals from pounds.

The legislation "would be damaging to our institution and to research and scientific progress generally," Purpura said in a letter dated Friday to Sen. Barry Keene, chairman of the judiciary committee.

"But it would be more realistic for you (committee members) to oppose this measure because of the very real disservice it does to all Californians . . ."

"If the bill is adopted, you would be faced with even stronger outcries from supporters of animal rights after they discover that the real dilemmas of humane treatment to animals have been exacerbated by well-intentioned but ill-conceived legislation," Purpura added.

Supporters of the measure have contended that the bill would prevent animals which had been kept as pets from being used in research.

"The legislation creates a great irony by increasing the number of animals which each year will be euthanized instead of being transferred to research facilities.

"Meanwhile, other dogs and cats will be bred specifically for use in the laboratory. Surely this is a grotesque misuse of resources, an abomination to conservationists," Purpura wrote.

Millions of dogs annually are euthanized at pounds because they are not adopted or reclaimed by their owners. For example, a report by a committee of the Santa Clara County Board of Supervisors said that one humane society alone— The Humane Society of Santa Clara Valley—euthanized nearly 75 percent of the 39,736 animals brought to the shelter in 1982.

Purpura said that legislation prohibiting the humane use of animals in research will swell already overcrowded shelters, increasing the likelihood that humane societies will have to put to death animals sooner.

-more-

April 15, 1983

"We are disturbed that that the proposed legislation ignores the fact that less than 5 percent of animals which are impounded annually nationwide are used in research and teaching while more than 95 percent are disposed of with no benefit whatesoever to life," Crowley said.

Crowley, Purpura and Krevans said they supported a measure backed by Assemblyman William Filante, R-Marin, which would require stringent standards of humane care for research institutions seeking to use pound animals. The measure, which has not yet been introduced in the legislature, would also establish a statewide identification system which would help persons locate stray animals at pounds. The measure, titled the Pet Protection Identification Act, would also give the person turning in an animal the option of refusing to allow the pound to release the animal for research.

Crowley said if Stanford were required to purchase all of its dogs and cats from commercial suppliers, the cost of these animals would at least quadruple from current levels of about $65,000 per year to $260,000 annually. Such an increase, Purpura said, could jeopardize already tightly funded projects.

In addition, Crowley said breeders could not provide the institution with sufficient animals and those that were provided "could not meet the qualitative needs of the biomedical community as in fact much research necessitates a genetically-mixed animal model rather than a pure-bred strain."

Alternatives, such as tissue cultures and computer modeling, cannot substitute for all biomedical research, although modern methods have reduced the number of animals, particularly dogs and cats, which are needed each year in research, said James Dewson, director of the Division of Laboratory Animal Medicine at Stanford.

For example, 795 dogs were bought for research at Stanford in 1978, compared with 506 in 1982. The number of cats in the same period dropped from 206 in 1978 to a total of 109 last year.

Dewson said his division houses between 5,000 and 10,000 animals at any given time. In addition, between 15,000 and 70,000 mice are held in special colonies.

The officials of both research institutions reaffirmed that they were committed to the humane care of animals.

Stanford currently is completing a $10 to $12 million centralized animal research facility which Dewson said "will provide state of the art animal care" exceeding current standards which are nevertheless adequate or better.

"Our campus is extremely concerned about the humane use of all animals in our research program," Krevans said in an April 14 letter to Keene.

Krevans said SB 883 "would have the effect of terminating many important research projects because if it pased we would be unable to obtain an adequate supply of dogs—an essential model in many scientific investigations."

STANFORD—

Stanford University Hospital's department of clinical social work is sponsoring a conference April 29 entitled "Oncology Social Work and Clinical Research." The event is one in a series planned as part of the continuing 70th anniversary celebration of social work at Stanford. These events are free of charge, and the public is invited.

Licensed clinical social workers Isabel Walker, Patricia Fobair, Sherry Feld, Jill Lehman, and Susan Weisberg will take part in the day-long conference, which is geared primarily toward other professionals in social work or related fields. It will take place from 9 a.m. to 4 p.m. at Fairchild Auditorium in the Medical Center.

Among the topics to be addressed are "The Value of Clinical Research in a Medical Setting," "Studying the Silent Majority," and "Medical Ethics in Research Design." Part of the afternoon will be devoted to small group workshops addressing more specialized topics.

Other events planned by the department are:

- On April 27—Rose Grobstein, C.S.W., will lead a seminar entitled "Genetic Counseling and Prenatal Diagnosis," from 2:30 to 3:30 p.m. in Faber Auditorium at Children's Hospital at Stanford.
- On May 20—Elizabeth Garifalos, L.C.S.W., Dr. Alan Ringold, and Pam Simmons, R.N., will conduct a workshop on "Adaptation to Hemodialysis," from 10 a.m. to noon in the Nursing Cottage at Hoover Pavilion.
- And June 24—"Approaches to Psychotherapy With Borderline Patients" will be addressed by Sandra Bacon, L.C.S.W. and Dr. Richard Laude, from 1 to 3 p.m. in TE-110 of Stanford's Psychiatry Building.

Further information is available by calling (415) 497-5091.

FARQUHAR HONORED BY AMERICAN COLLEGE OF PHYSICIANS

STANFORD—

Dr. John W. Farquhar, director of the Stanford Heart Disease Prevention Program (SHDPP), was honored by the American College of Physicians (ACP) Monday (April 11) for research linking changes in eating and smoking habits with decreased incidence of cardiovascular disease.

Farquhar, a professor of medicine in the Division of Family, Community and Preventive Medicine, received the 35th annual James D. Bruce Memorial Award, which recognizes outstanding contributions in the field of preventive medicine.

Former recipients include polio vaccine pioneers Jonas Salk and Albert Sabin.

"The Challenge for Physicians in Newer Forms of Preventive Medicine" was the title of Farquhar's Bruce Award speech at the San Francisco meeting.

Farquhar, who founded SHDPP in 1971, helped develop an interdisciplinary approach to prevent and control heart disease. One aspect of this is a public health project in several California cities intended to educate people, primarily via newspapers, radio and community classes, on the health benefits of eating better and smoking less.

The recipient graduated in 1952 from the University of California School of Medicine at San Francisco and then completed his training in internal medicine and cardiology at UCSF and the University of Minnesota.

Other Stanford participants at the annual meeting held in San Francisco included Drs. Edwin Alderman, associate professor of cardiology; William Hancock, professor of cardiology; and Jack Remington, professor of infectious diseases; Maurice Fox, clinical professor of medicine; Kate Lorig, R.N., Dr.P.H., Arthritis Center; Ronald Pearl, physician specialist in medicine; Eugene Robin, professor of medicine; and Howard Spiro of the Center for Advanced Study in Behavioral Sciences.

INTERNSHIP MATCHING PLEASES STUDENTS

STANFORD—

Internship match day at Stanford University Medical School was a happy occasion for 76 percent of the graduating students who were appointed to one of their top three hospital choices.

According to Dr. Elizabeth M. Short, associate dean of student affairs, this shows improvement over the last decade's average of 70 percent.

What's more, 53 percent of the students were appointed to their first hospital choice, compared with the last decade's average of 44 percent.

About 18 percent of the graduates will be staying at Stanford. About 64 percent will be interning at university hospitals.

Internal medicine is the number one specialty choice, with more than 55 percent opting for it. Other popular specialties include surgery and family practice.

"In a time when the number of medical school graduates exceeds the number of internship positions, our graduates did extremely well," Short said.

ASSOCIATE DEAN OF STUDENT AFFAIRS TO JOIN ASSOCIATION OF AMERICAN MEDICAL COLLEGES

STANFORD—

Dr. Elizabeth M. Short, associate dean of student affairs, announced she will be leaving Stanford University School of Medicine for the Association of American Medical Colleges (AAMC) in Washington, D.C.

A new associate dean of student affairs has yet to be named.

Her new position as director of the association's division of biomedical research and faculty development, and associate director of the department of academic affairs, will begin this summer.

In her new role, Short said she will deal with issues affecting the nation's academic medical centers, ranging from funding sources for biomedical research to faculty development and medical education.

"I think it's an exciting opportunity to obtain a national perspective on issues of concern to faculties and students," Short said. "It's a time when changes are occuring in public policy that will have major impact on academic medical centers."

Short will bring to her new position her experience in academics and administration at Stanford, and in shaping public policy on biomedical research as a member of the American Federation for Clinical Research (AFCR). She is on the AFCR executive and public policy commmittees, and is editor of its journal.

"Stanford is an exciting medical school, and I feel privileged to have worked with the students here. I will bring to the AAMC job perspectives gained at an excellent academic institution," she added.

Short has been associate dean of student affairs since 1978. "She has made substantial contributions to the clinical education of Stanford's medical students," said Dr. John P. Steward, associate dean of student affairs. "Two of her major responsibilities have been assigning students to clerkships and writing letters to support students' applications for internships. In both of these important and major roles she has been an extraordinarily valued member of the Office of Student Affairs, and will be missed."

Short has been an assistant professor of internal medicine, specializing in medical genetics. She came to Stanford in 1973 and served as chief resident in medicine the following year, after which she became a faculty member.

Short received her medical degree from Yale University School of Medicine. She completed her residency training in medicine and research fellowship in human genetics there also.

VA BEGINS REVIEW OF LAB ANIMAL ACCIDENT

(Editors, news directors: The following was sent on Business Wire Wednesday afternoon)

STANFORD—

An animal welfare panel at the Palo Alto Veteran's Administration Hospital will review an accident which resulted in injuries to a research dog, officials said Wednesday (April 6).

Barbara Gleason, administrative officer for research at the VA hospital, said a general investigation of VA animal care facilities was inappropriate, since the animal's condition appeared to have resulted from an isolated incident and did not indicate more generalized difficulties.

"We are researching this incident basically to reassure everyone that while the accident involving this dog was unfortunate it does not reflect negatively on the high quality laboratory animal care provided at the VA center," Gleason explained.

Carolyn Reed, veterinarian at both Stanford Medical Center and the Palo Alto VA, said the dog was attacked by another dog in an adjacent cage in late March. The dog was being properly treated when it was removed by a medical student from a cardiovascular research lab, Reed said.

It was later euthanized after the student, who worked in the lab, brought the dog to a private veterinarian who said he didn't think the dog would recover.

At an April 1 news conference, officials of the Santa Clara County Humane Society contended that proper treatment may not have been provided the animal. In a position statement the society contended that after investigating the incident, the organization planned to file charges with the Santa Clara County district attorney's office under a county ordinance covering animal abuse.

On Wednesday, Larry G. Kemp, the society's chief humane officer, said the incident "is still under investigation by the Santa Clara and Peninsula Humane societies."

Deputy Dist. Atty. Robert Harpainter, supervisor of the Santa Clara County DA's Palo Alto office, said in an interview that he had spoken with Kemp and at least one other humane society official earlier in the week.

"At this point, I don't plan on doing anything further," Harpainter said Wednesday. He said his office lacked jurisdiction because the county ordinance didn't apply in the Palo Alto city limits where the VA is located.

-more-

A "fact sheet" issued at the humane society's news conference said the dog was found "in the Stanford Research Center."

However, Gleason said the VA's panel would investigate since the VA was responsible for the dog, which was owned by the VA and participating in a VA-sponsored study.

The internal review would be conducted by VA personnel, she said. Chairman of the panel would be Malcolm Anderson, a radiologist on the Stanford Medical Center faculty assigned to research and patient treatment at the VA. Anderson is chairman of the VA's Animal Care Subcommittee of the Research and Development Committee.

Peter Barran, the medical student who removed the dog, said he had worked in the VA lab for 10 months and had not seen any similar incidents.

Reed said the dog had been bandaged immediately after it was bitten about a week before it was brought home by the student. She said bandages were removed March 23, the day before the dog's removal from the VA, and that she determined the best treatment was to let the bite wounds drain.

Surgical incisions in the groin area had been sutured but may have opened after the March 23 exam, the veterinarian said last week.

Reed said the dog was bitten by a dog in an adjacent cage. Because of residual anesthesia, the injured animal was unaware of the biting and didn't shift positions, "a regrettable, but fortunately unusual occurrence," Reed said.

Barran said he contacted Reed the night he removed the animal and asked her to come to his apartment to treat it. Reed said she refused and requested instead that he return the animal to the lab where she could properly treat it.

The dog was participating in an an experiment intended to perfect techniques for repairing and replacing blood vessels.

The VA study was being conducted by faculty members and other researchers from the Stanford Medical School. Most VA physicians have dual appointments at the university.

James Dewson, director of laboratory animal medicine at Stanford, said no university probe was planned since the incident did not involve a Stanford research project.

"If a similar accident were to occur at Stanford, our Panel for Laboratory Animal Care would conduct an immediate and thorough review of the specific incident," Dewson said.

Stanford's participation in VA research stems from a contract with Stanford to faculty physicians for patient treatment and research at the VA.

Reed is chief veterinarian at the university and also works part time supervising veterinary care at the VA, where she reports to VA officials, Dewson said.

LEARN TO LOVE EXERCISE!

STANFORD—

A structured workshop for people who want to start and maintain a regular physical exercise regimen will be offered at Stanford University on 10 consecutive Tuesday evenings beginning April 19.

Open to the public, the newly developed workshop will provide information, individual assessment, support, and both behavioral and cognitive strategies designed to get participants to the point where exercise provides its own self-sustaining incentive and reward.

No exercise will actually be engaged in during sessions, said leader-coordinator Dr. Fritz Bottjer of the Behavioral Medicine Program. Participants will undergo some testing, including before-and-after body mass, psychological, and cardiovascular functioning.

In addition to attending sessions, participants will be expected to read handouts, engage in exercises of their choice, and to complete assessment and other assignments.

According to Bottjer, success at maintaining regular exercise suitable to the individual has been linked to a variety of positive physiological and psychological outcomes. These include:

- improved cardiorespiratory functioning and resistance to disease;
- improved appearance, body image and self-confidence;
- enhanced strength, energy and sports performance;
- appetite and weight control;
- lowered incidence of depression;
- improved sleep;
- heightened sexual interest and appeal;
- improved management of stress;
- the general maintenance of a healthy, attractive and youthful body.

Sessions will run for two hours, and the required fee is due at the first session. For the program overview or further information, contact Bottjer at (415) 497-7340, or write to him at the Behavioral Medicine Program, TD 205, Stanford University School of Medicine, Stanford, CA 94305.

Prospective participants are requested to call or write by April 15.

"I CAN COPE" COURSE FOR CANCER PATIENTS AND FAMILIES

STANFORD—

A useful, practical course of the American Cancer Society, for people dealing with the implications of living with cancer, will be offered at Stanford University Medical Center on eight consecutive Wednesday evenings beginning May 4.

Nutrition, body image, rehabilitation, and sexuality are among the topics covered by the course, which is intended for cancer patients and their families. "I Can Cope" seeks to help participants be more aware of their own strengths in coping with cancer, live within limits, and like themselves. It provides a setting where ideas and concerns may be shared and discussed.

The unique course deals with daily health problems as well as legal and work issues, and allows participants to express and resolve their feelings. Free of charge, it will be taught by a team of Stanford oncologists, nurses, dietitians, physical and occupational therapists, and social workers. Information about and access to appropriate community resources will be provided.

"Participants in this course are given an opportunity to realize they are not alone in their adjustments to everyday life," according to co-leader Sherry Feld, L.C.S.W. "Those with cancer and their loved ones need ways to cope with fears and anxieties as well as the disease."

Implemented nationally, she said, the patient education program is helping move people from asking, "What can I do?" to stating, "Here's what I can do!" The course supports the premise that increased knowledge about cancer decreases anxiety and increases a personal sense of participation on the part of the patient and his or her "significant others," with the medical system.

The course was developed by Judi Johnson, R.N., and Pat Norby, R.N., for the Minnesota Division of the American Cancer Society. The course content starts out with very concrete information about cancer, presented in an educational format.

Sessions will be held from 5:30 to 7:30 in room TF 122c of the Psychiatry Building. Susan Weisberg, L.C.S.W., will co-lead. Enrollment is limited. For further information and registration, call the Department of Clinical Social Work by April 27, at (415) 497-5091.

PUBLIC CONFERENCE ON EATING DISORDERS TO BE HELD AT MEDICAL CENTER JUNE 25

STANFORD—

A conference on eating disorders, sponsored by Stanford's department of psychiatry and behavioral sciences, is scheduled for Saturday, June 25.

The behavioral medicine program is presenting the day-long conference in response to growing community concern about obesity, anorexia and bulimia, to broaden public understanding of such disorders and describe the most current treatments available, said Dr. Stewart Agras, director of the behavioral medicine program and one of the speakers at the conference.

Anorexia, a condition usually found in girls and women, is characterized by a distorted body image and resultant adherence to a rigid, extreme diet which leads to excessive weight loss. Bulimia, also primarily affecting women, tends instead to compel people to eat excessive amounts of food. Most binge and then purge themselves of the food by inducing vomiting, or taking laxatives or diuretics.

Ongoing research continues to question what connections exist between the two disorders, or if in fact they are different facets of one illness.

At the conference, Dr. Agras will give an overview of eating disorders and will specifically address obesity. Speaking on bulimia will be John Bachman, Ph.D., director of the behavioral medicine clinic. Dr. Barr Taylor, associate director of the program, will discuss anorexia nervosa. All three regularly see patients in the eating disorders clinic.

In addition, other faculty and staff from the eating disorders clinic will participate in afternoon small group discussions of each of the topics.

The conference, scheduled to last from 9:30 a.m. to 4 p.m., will be held in M104 of the medical school. Pre-registration is recommended, as space is limited. A fee is charged and will be payable at the door.

Lunch will be available for purchase at the medical center and on campus.

For further information or to register, call (415) 497-7871.

CHILDREN CAN SEEK COMFORT IN PARENTS' BEDS, PSYCHIATRIST BELIEVES

STANFORD—

Many children apparently crawl into their parents' bed when scared or sick at night, and that's not necessarily a bad thing, a Stanford University researcher contends.

The opinion of Dr. Alvin A. Rosenfeld, assistant professor of psychiatry and behavioral science, follows a study of 576 children aged 2 to 10. The view differs from that of renowned pediatrician Benjamin Spock, who wrote the all-time best selling guide for parents.

"Better not to let the child in your bed," wrote Spock in the 1976 edition of *Baby and Child Care* "... always bring him promptly and firmly back to his own bed."

Rosenfeld believes that letting a feverish or frightened child stay in the parents' bed for a while can sometimes be helpful. Far too much attention, Rosenfeld said, has been paid to actions rather than the attitudes which motivate them.

"And Dr. Spock agrees," said Rosenfeld who has been corresponding with the noted baby doctor. In a recent handwritten letter, Spock told Rosenfeld:

"I agree entirely that the pathological effect of any parental procedure comes from the attitudes, not the procedure. But how do you explain that in a book for all parents?"

Explain for the public is what Rosenfeld now is trying to do.

"I believe my study is important, because we are just beginning to do real research on children's sexuality—on relationships and the foundations of intimacy. Most sexual research to date has really been animal research in the sense that it looks at biological or mechanical data, not at information about how people feel about each other or the needs and wishes that sexuality fulfills.

"Many psychiatrists can cite instances of patients who have behavior problems who slept with their parents when children. But no one before has studied how typical, non-pathological families behave in this context."

-more-

May 31, 1983

Rosenfeld's study, published in August 1982 in the Archives of General Psychiatry, was conducted at two daycare centers and a summer camp in an affluent community near San Francisco. It is one part of a much larger study of sexual and affectional life in normal families.

The study showed that 68 percent of the children came to their parents' bedroom when they awoke ill or frightened, and 92 percent of the parents let their children come into their bed.

None of the families reported serious behavior problems, Rosenfeld said. The vast majority of parents said they were able to return their children to their own beds during the night, after the youngsters were reassured.

"I'm not contradicting Dr. Spock, who must be respected for humanizing child care in America. I'm simply trying to state that responsible parents must be the judge of what is best for their own child, and I think this study is an indication that they do."

"People look to so-called experts for answers, and these authorities need data on which to base their answers.

He said that one misconception on the effects of co-sleeping or other childraising procedures stems from taking extreme cases where the child comes to psychiatric attention. These cases are then pointed to as examples of how a practice is supposed to be deterimental.

"I can recall a colleague who told of a patient who became a pornographic film maker after sleeping regularly in his parents' bed and watching them have sex about 1,800 times during a 15-year period.

"Of course that is harmful. Sex is much too confusing, exciting and stimulating for children to view. And taking your child into bed every night for 15 years is certainly highly pathological. It also shows no common sense, which is what we're really talking about. But parents shouldn't panic if their children stumble in on them when having sex; that's an isolated, undoubtedly unavoidable incident which need not be a cause for alarm. And if the parents do not overreact, there is no reason to believe their children will ultimately suffer.

"The basic rule of thumb should be that parents should do what is comfortable for them in a deep sense. If they truly feel comfortable having their children see them nude, for example, it might be appropriate behavior within the family. Finnish people are raised that way. But parents shouldn't walk around nude feeling uncomfortable just because intellectually they believe it would be a good idea and will somehow make their children free."

CENTER PROPOSED TO EXPLORE NMR APPLICATIONS IN MEDICINE

STANFORD—

A new center to explore applications of nuclear magnetic resonance (NMR) in medical research and practice received unanimous approval Friday by the executive committee of the Stanford University School of Medicine.

"NMR, co-invented by Stanford's Nobel laureate Felix Bloch in the mid-forties, has evolved into one of the most extraordinary body-imaging tools of the future," said Dean Dominick P. Purpura. "It's therefore fitting for Stanford to establish a center dedicated to the continuing development of NMR."

The proposal for the new center, estimated to cost $3.3 million, will now move through the University administrative review process before it is submitted to the Stanford Board of Trustees for approval in the fall, said Purpura.

"I view the development of the NMR center as a component of a much broader based program in molecular and genetic medicine which is currently in the planning stages," Purpura said. "Clearly we are preparing for entry into the twenty-first century with an approach that would permit rapid transfer of basic science information to the clinical domain.

"NMR is but one aspect of molecular medicine and an important one. The proposed NMR Center will be the first of its kind anywhere, and Stanford should maintain this leadership as a tribute to Professor Bloch."

New to medicine, but long used by physicists and chemists, the analytic technique of NMR depends on the ability of chemical elements to respond to intense magnetic fields and bursts of radioenergy by emitting signals that indicate the structure of molecules or the state of health in human organs. NMR needs no hazardous X-rays, no injections, no drugs and no surgery to perform its detective work. In medical jargon terms, it is noninvasive, and therefore safe.

In 10 minutes or less, NMR can produce computer-generated images of cross sections of a patient's whole body, or of a single organ, more completely than CT and PET scanners can. Moreover, it can deliver chemical as well as physical information.

-more-

5-31-83

"The technique has enormous potential as a tool for diagnosis and for evaluating biochemical changes in the body during treatment," Purpura said. "It will have a particularly dramatic impact on the analysis and treatment of a variety of neurological and psychiatric disorders because of its ability to image metabolism in different brain areas noninvasively."

NMR instruments use extraordinarily intense magnets cooled by liquid helium to temperatures of about 450 degrees below zero. The magnets generate fields more than 40,000 times as intense as the earth's magnetic field.

Stanford already has a strong program investigating biological applications of NMR under the direction of Dr. Oleg Jardetzky, professor of pharmacology. The program is already building one of the most powerful laboratory magnets in the world to generate magnetic fields nearly 300,000 times more intense than those of the earth. The powerful new NMR magnet will be used for biochemical studies, not for human patients.

But both this instrument and three additional NMR machines will be housed in the proposed center. The building will be shielded from outside radio waves, while a different type of shielding will prevent the scanners' magnetic fields from affecting electronic equipment in the immediate area.

Stanford researchers will use the clinical NMR machines for body-imaging studies, and metabolic studies, looking at how disease changes the body's use of energy. Metabolic changes in the body often occur before any change in anatomy that could be picked up by using X-rays, Purpura said.

The proposed NMR center, whose use will not be limited to biomedical researchers but will be available to all University departments, will be governed by a policy board, Purpura said. A three-member directorate with one member designated as the director will guide the day-to-day operations.

The directorate and governing board will represent the basic sciences, the radiology department and other clinical departments.

Funding for the proposed center will be sought from private sources and federal government, he added.

PHYSIOLOGY PROFESSOR GEORGE FEIGEN DIES

STANFORD—

George A. Feigen, a Stanford University physiologist whose wide-ranging interests joined the fields of immunology and pharmacology in more than 44 years of teaching and research, died at Stanford University Hospital Sunday evening, after suffering a ruptured aorta. He was 66.

"He was an international leader in research who literally trained students from throughout the world," said Eugene Robin, acting chairman of the department of physiology. Head of the department's PhD. training program for the last ten years, Feigen was "a man of the highest standards, who insisted that the highest level of performance in hands-on training in the lab was critical to the education of excellent young scientists," said Robin.

Born in Rostov, Russia in 1916, Feigen came to the United States in 1930. Doctorate degrees in physiology and immunology from the California Institute of Technology in 1947, sparked a career that explored the effectiveness of various blood substitutes, examined the mechanisms of shock triggered by severe allergy, and investigated the effects of allergic reaction on the heart and blood vessels.

Anaphylactic shock—the most severe allergic response— was Feigen's special area of expertise. In 1967, scientists identified a special protein, called immunoglobulin E (IgE) which plays a key role in triggering an allergic reaction.

Through their study of guinea pigs, Feigen and his colleagues discovered the biochemical reactions that IgE uses to unleash histamine— a potent chemical, normally sequestered in certain cells of the body. Sudden release of histamine into the bloodstream can produce severe and sometimes fatal symptoms.

Feigen spent two decades seeking to understand why a defense system usually so powerful in protecting a person from infection, "goes overboard" under certain circumstances, producing poisons detrimental to the host.

One recent project explored theories that certain cases of female infertility may result from immunization to sperm. Feigen showed that human fallopian tubes are extremely sensitive to histamine, and that the the intensity of an anaphylactic response varies at different phases of the menstrual cycle.

Researchers in Feigen's laboratory are also currently studying the effects of vitamin C on the immune system.

Robin praised Feigen as an outstanding researcher and teacher of laboratory science.

"As a teacher he was feisty and demanding, but extremely loyal to his students," said Robin. "George Feigen radiated integrity."

Feigen joined the Stanford faculty in 1949, after several years of teaching at Cal Tech and the University of Southern California. He spent a year at the University of Oxford in 1956-57 as a traveling scholar of the American Heart Association, and returned to Oxford in 1963-64 as senior post-doctoral fellow, courtesy of the National Science Foundation.

A member of numerous scientific societies, including the American Physiological Society, Sigma Xi, and the New York Academy of Sciences, Feigen served often as guest teacher and lecturer to universities throughout the world.

He is survived by his wife of 35 years, Priscilla R. Feigen. Arrangements for a memorial service were pending at press time.

Dr. Wood can be reached directly at (415) 497-6254.

EAT AND PLAY YOUR WAY TO SLIMNESS!

STANFORD—

Encouraging people to ultimately eat more, not less, should be the goal of any worthwhile weight loss program, contends Dr. Peter Wood, deputy director of the Stanford Heart Disease Prevention Program (SHDPP).

What sounds like a unique twist to modern theories of weight control stems from Wood's scientific observation that slim people generally eat more—and do more exercising—than their overweight friends.

As Wood explains in his new book, *The California Diet and Exercise Program* (288 pages, Anderson World Books, Inc., $13.95), the problem with most popular diets is that they focus too heavily on the wrong side of the calorie equation.

"The idea that being overweight is due to, and sustained by, eating inordinately large amounts of food has been with us for many centuries, and dies hard: the gluttony model," the professor of medicine (research) said in an interview.

Actually all it takes, Wood said, is 14.4 calories too much each day for 30 years to store up 45 pounds of extra fat by age 50. This is about a fifth of a banana too much each day, hardly an amount fit to prohibit or prescribe.

"Since the early 1900s Americans have actually decreased their food intake, become more sedentary, and grown fatter. It's clear that the problem is not eating too much, but exercising too little," Wood observed.

In studies at the SHDPP, Wood and colleagues compared lean, middle-aged runners (40 miles per week) and tennis players (10 hours singles per week), of both sexes, with average, randomly selected men and women.

-more-

5-23-83

"The case of the tennis playing women was particularly striking," said Wood. "They reported eating about 62 percent more than their sedentary counterparts." They have to eat a lot, he said, to remain very active.

Wood's book sets forth a systematic approach to weight control, intended for those who've been moderately overweight as adults. Extending over a full year, the program is purposely gradual. "People can be easily discouraged if pushed too fast to change, and that's why so many give up on other diets."

Also, he added, "Most experts agree that a true loss of one to two pounds of body fat per week is the fastest you should go."

The sort of exercise Wood advocates is "play"—that which is enjoyable. He urges people to vary their activities and exercise in company, increasing social contacts as well as physical benefits.

"Of course," he said, "the more vigorous activities burn fuel faster. Jogging, cycling and swimming are champion fat burners." The London born researcher has been an avid runner himself since the age of seven, and authored *Run to Health* in 1980.

"But remember that if you have the time, a mile walked slowly will use nearly as many calories as a mile run fast," he said.

In Wood's program, menu plans work side by side with play plans, the two intricately dependent on each other. Caloric intake is decreased somewhat at the beginning of the year, but gradually increases with level of play, until by the end of the program the individual is both playing more and eating more than before.

"Rewards are built in at intervals," Wood explained. "At the end of the year the body is in balance, neither gaining nor losing calories (or fat). This is the state we need to reach, one of equilibrium."

Wood believes that a full year on his program will accustom the individual to a new lifestyle, ensuring weight maintenance rather than the instant gains so commonly experienced after dieting.

He pointed out that an active lifestyle brings with it numerous health advantages besides weight loss. These include improved cholesterol pattern, decreased inclination to smoke, muscle build-up, benefits to bones and joints, improved heart function and respiratory function, lower resting pulse rate, less constipation, increased resting metabolic rate, improved sleep, and improved mental outlook.

Eating heartily also, Wood said, is what Nature intended for human beings. "There are many disadvantages and some dangers in the permanent low-calorie approach to weight control.

-more-

"In my view, low-calorie diets should be used sparingly and therapeutically to achieve loss of accumulated fat; *not* prescribed as a permanent, desirable, modern, with-it, and thoroughly admirable way of life," he said. "Life—especially Californian life—requires food!"

And, he added, "When your body gets a lot of food and exercise, the natural mechanism for balancing the two works very well." As an example, Wood said he has to be careful that his own weight doesn't go too low.

Advantages of hearty eating include a higher resting metabolic rate, improved nutrition (provided that foods are chosen wisely), less constipation, and more enjoyment.

Also, "Several long-term scientific studies now agree that people who go on to suffer heart attacks are more likely to have been eating *less*, years earlier, than similar people who remained well," said Wood.

"What the data are probably telling us is that the people in the studies who were eating more were also more active and leaner; and these two attributes accounted for their reduced heart disease rates."

Wood designed his weight loss program with safety and efficacy in mind, as well as a special concern for the older person. His plans provide ample amounts of nutrients (protein, vitamins, minerals) and other components to maintain good health (like fiber), and are low in items that should be low (salt, cholesterol, saturated fat).

"Many natural foods are beneficial to health, and may help, along with good exercise, to ward off the major chronic diseases of the age, heart disease and cancer." While dieting, Wood said, many people may inadvertently increase their risks of future disease by omitting some basic food essentials.

This is where most popular and self-designed diets go wrong, he added. "But unfortunately, people ask more of car salesmen than they do about new diets. Some of the fads that have been promoted are outrageous—but you name it, they sell it."

Besides becoming well-informed oneself, it's a good idea, Wood said, to inform one's doctor when embarking on a considerable change in lifestyle. "Those more than 80 pounds above their ideal maximum, or having known major health problems, should certainly consult with their medical advisors before beginning any weight loss or exercise plans."

Editors: This story is being released simultaneously with a story on Stanford researcher Dr. Peter Wood's new book on excercise and diet.

STANFORD PHYSICIAN SPEAKS OUT ON NUTRITION

STANFORD—

"Low calorie diets put people in a semi-starvation state," warns a Stanford University scientist in a newly published book.

"They affect the metabolism, including brain activity," said Dr. Keith Taylor, professor of medicine. "In the extreme, they cause people to become dehydrated, go into stupor, or even become comatose."

Safe diets, he continued, are those in which none of the essential nutrients is left out, and in which people lose weight at a slower, steady pace. Increased physical exercise, he stressed, can help a lot.

The new book, *Clinical Nutrition*, (631 pages, McGraw-Hill Book Company, $21.95), was co-authored by Taylor and Dr. Luean Anthony of the University of Texas Health Science Center.

"We wrote *Clinical Nutrition* to be a reference book, but also to relay the message that physicians need to think about patients' nutritional status whether they're sick or well," Taylor said in an interview. "Like a medical textbook, each chapter treats a different body system and includes the basic medical information about each one. The difference is that we emphasize nutritional matters in relation to each system."

Nutrition is a major factor contributing to health and disease, but unfortunately, physicians tend to overlook its importance, Taylor observed.

His book, he said, may be the first all-inclusive medical textbook focusing on the importance of what people eat.

5-23-83

-more-

"Our goal is to provide physicians, medical students, nurses, and all health care providers the information they need to be able to discuss eating habits and educate their patients," Taylor said. When a patient asks about a diet, for example, the physician has got to know about it, he added.

"You've got to know why that specific diet is good or bad," Taylor said. "If you've never heard of it, you lose your credibility with the patient. Then even if you give good advice, the patient most likely won't listen."

Taylor extensively evaluates all the popular diets. "Diets on which people eat as few as 300 calories a day, such as the liquid protein diets, are dangerous," he said. "Many deaths have been reported, especially among young women, probably due to cardiac complications.

On a more general note, Taylor and Anthony speculate that some of the diseases of western civilization may in part be due to a move away from the bushman's diet. In the past 10,000 years, agriculture and cattle herding have led humans to adopt diets possibly including too much animal food. Early man's diet, he said, consisted mostly of vegetables with some animal food. By comparison, modern man's diet is probably much more restricted.

While Taylor said all essential nutrients are probably known, the ideal balance of these nutrients, and the effects of an imbalance on the human body still remains a mystery. "In this area," Taylor concluded, "we've still got a long way to go."

STANFORD MEDICAL GROUP GETS BETTER WITH AGE

STANFORD—

With more than a year of successful operation behind it, the Stanford Medical Group is looking at ways to expand and improve its services, according to co-founder Dr. Michael Jacobs, clinical associate professor of medicine.

Established by Stanford University Medical School's Department of Medicine in 1981, the clinic provides members of the Stanford and surrounding communities the opportunity to receive high quality medical care by faculty physicians without being part of the teaching format.

Two more physicians—Dr. Susan Kritzik, currently a staff physician at Palo Alto Veterans Administration Medical Center, and Dr. Terrigal Burn, currently a clinical instructor in the division of general and internal medicine, and department of mental health and community nursing at University of California, San Francisco—are scheduled to join Jacobs and Dr. Scott Wood in the university-based group practice this fall. Co-founder Dr. Armand Gelpi, clinical professor of medicine, will be leaving the clinic.

The new physicians will enable the clinic to expand its consultation service, which currently serves all clinical departments at the Medical School and Northern California physicians, as well as its medical-psychiatric inpatient service, Jacobs said.

"We also need to address the question of what a service-oriented practice group is doing in what is primarily an academic center," he continued. "We have to integrate our practice with the academic goals of the medical center without risking the quality of care."

The way to accomplish this, Jacobs explained, is to assign select senior residents to work with patients in the clinic. This will be done initially with the inpatient consultation service, followed by "establishing an outpatient rotation for carefully screened senior medical residents especially interested in the practice of primary care internal medicine.

"This would be a natural step for someone who plans to go into private practice within the next few months," he said.

-more-

5/20/83

Jacobs added that he hopes the group physicians will be able to start documenting original clinical observations they experience. This too, he said, will contribute to the "scholarly credibility" of the service-oriented group.

The idea for the group practice evolved in response to individuals' expressed desire to have a full-time faculty member as their personal physician. SMG is based on similar programs in existence at about half the nation's medical schools. Jacobs and Gelpi formed the original core of physicians, aided by about 12 affiliates from the department of medicine. The group, which also includes a full-time nurse, offers patients complete outpatient and inpatient care on a 24-hour basis.

The faculty member chosen to be the personal physician is fully responsible for their patient's care, Jacobs explained. The physician arranges consultation with other medical specialists if needed, and is available for outpatient visits in the clinic during regular weekday office hours. If hospitalization is necessary, the physician admits the patient to Stanford University Hospital, and assumes the attending, or teaching function on one of the teaching services.

During its first year of operation, the group received more than 3,200 outpatient visits, Jacobs said. About 40 percent of the referrals came from Medical Center physicians, while about 60 percent came from outside physicians.

"The group achieved a balanced budget in its first year, which is a distinctly unusual occurrence in comparable programs," he added.

In 1982, Wood joined the group as the third physician. He cares for Stanford University Hospital employees' job-related illnesses, and performs all intake examinations on Hospital personnel.

"Attaining this contract between the SMG and the Hospital was important because it justified adding a third full-time physician after only a year of operation. Also, Wood is in an ideal position to attract new patients to the group," Jacobs observed.

The group, which is administratively and financially independent, is also planning to move into new office space, as part of the Boswell Building renovation plan. The $6.5 million construction, equipment, and remodeling program will upgrade the physical facilities of the Stanford University Clinics. The clinics serve as offices for the Medical School faculty. They receive about 135,000 visits per year.

DONOR SHORTAGE REDUCES HEART-LUNG TRANSPLANTATION

STANFORD—

Scarcity of donors has restricted Stanford's heart-lung transplant effort, the program's principal investigator said Wednesday (May 18) after the first such operation in more than four months.

"We have been hoping to perform about 12 such transplants a year, but today (Wednesday) was the first time we have found a suitable donor since January," making it only the second heart-lung transplant this year, said Stuart Jamieson, assistant professor of cardiovascular surgery and head of the heart/lung program.

"Three of the 10 persons waiting for new hearts and lungs have died since last January, and we can expect to lose more unless potential donors are brought to our attention."

The physician said only about 20 percent of potential heart transplant donors are suitable for the double transplant operation, which has been performed 12 times at Stanford since March 9, 1981. Eight of the patients, including the four most recent before Wednesday, have returned to their hometowns and are doing well, Jamieson said.

The difficulty, Jamieson said, is that the lungs often become damaged before they are removed and can be used in surgery. Pneumonia is the most common condition which afflicts brain dead donors while mechanical equipment keeps their hearts beating and their lungs ventilated until the organs are transplanted into a recipient, Jamieson explained.

When the lungs are found unsuitable, the heart often can be used for a heart-only transplant. Eight such operations have been performed since the last heart-lung operation was performed, bringing the heart-only total at Stanford to 263 since January 1968.

Heart-lung transplantation is newer and was made possible by recent improvements in medication intended to prevent patients' bodies from rejecting their new organs. A new drug, cyclosporine, permits healing of the windpipe.

May 19, 1983 -more-

"Heart-lung transplantation has been proven to be helpful to a small number of patients who otherwise would face certain death without the procedure," said Jamieson. "But our ability to perform the operation is limited because of our difficulty in having potential donors brought to our attention."

Donors, he said, must be brain dead but free of other disease. Their families must give permission to donate their organs after death.

"Our whole problem," Jamieson said, "depends on public awareness of the need for this precious resource."

The most recent heart-lung patient was identified as Fernando Flores, 32, of Mercedes, Texas, who was reported in critical but stable condition after the five-hour operation. On Thursday morning he was awake and breathing unassisted.

"He still has a long way to go, but he is doing well," Jamieson said.

Flores, who had worked as a career counselor, suffered from a ventricular septal defect. A hole present from birth allowed blood to flow between the chambers of heart, causing a volume overload of blood which eventually damages the lungs. The condition ultimately is fatal unless both the heart and the lungs are replaced.

A 38-year-old Visalia, Calif., man, Dennis Vinyard, was the last heart-lung transplant recipient at Stanford. He has returned home after hospitalization and treatment following up his Jan. 10 operation, Jamieson said.

Stanford's first heart-lung transplant, Mary Gohlke, now 47, has returned to her Mesa, Ariz., home. She has worked as a newspaper advertising executive and has been working on a book recounting her experiences.

"We'd like to be able to perform more of these operations," said Jamieson. "The critical factor is donors."

The physician stressed that hospital personnel can play a critical role in identifying potential recipients and explaining during a very stressful time to families how the brain dead patient's organ can be used to save someone else's life.

Medical personnel or families who may have a potential donor may call Stanford's Department of Cardiovascular Surgery, (415) 497-5771, 24 hours a day.

"We are able to accept donors from throughout the United States or Canada," Jamieson said.

SYMPOSIUM HERALDS MOLECULAR ANSWERS TO QUESTIONS OF DISEASE

STANFORD—

Genes that can trigger cancer, the biology of learning and memory, and cell receptors that help the body fight heart disease all played a part in what Stanford Medical School Dean Dominick Purpura called an "academic festival" held at the medical center Friday (May 13).

Six scientific sleuths from around the country, prominent in the search for molecular answers to questions of health and disease, profiled their research for an overflow crowd in Fairchild auditorium in a day-long symposium entitled "Perspectives in Molecular and Genetic Medicine."

Just as the invention of the microscope opened a window on a world too small for the naked eye, the new biochemical tools of geneticists are permitting scientists to go several steps further and explore the interactions of molecules in both healthy and diseased tissue. Researchers in a variety of fields are now snipping molecular strands of genetic material into component parts, and recombining them in ways that offer a new, deeper level of understanding.

"We are, to a large part, what we are because of what we've learned. But only in the last decade has learning become something that we can study on a cellular level," said Eric Kandel, a neuroscientist from Columbia University whose work with James Schwartz has revealed fundamental mechanisms of learning in sea slugs.

The celebration of recent advances in genetics, biochemistry and medicine was prompted, Purpura said, by the university's recent commitment to a "Center for Molecular Genetics," an interdisciplinary program planned for development at Stanford within the next several years.

"It is critical to be far-sighted," President Donald Kennedy later told a gathering of alumni, "if we are to lead phase two of the wave of breakthroughs in biochemical research in the same way that we have led phase one."

"Phase two" of the revolution will involve further exploration of basic science, Purpura said, coupled with applications of that knowledge in ameliorating disease.

A century-old search for a genetic basis for cancer may have found its first fruits in the recent discovery of "oncogenes," genes found in certain animal tumors, and thought also to exist in some human cancer cells, that by their very presence convert a healthy cell to a cancerous one.

-more-

5-17-83

"Tumor viruses have revealed to us a set of genes whose activities may lie at the heart of every cancer, no matter what its cause," said J. Michael Bishop, a microbiologist from the University of California, San Francisco. "We view these genes as the keyboard on which many different carcinogens can play, whether they be chemicals, X-rays, the ravages of aging, even viruses themselves. An enemy has been found—it is part of us—and we have begun to understand its lines of attack."

Bishop uses viruses as experimental tools "to ferret out the universal processes that may cause a cell to run amok". Michael S. Brown, a geneticist at the University of Texas Health Science Center at Dallas, spoke of using similar genetic tools to get an inside look at arteriosclerosis—an often fatal clogging of the arteries.

"Mike Bishop mentioned that one out of four people in the United States die from cancer. Twice as many die from hardening of the arteries," said Brown. "It's an insidious disease that begins in the teenage years, but usually causes no symptoms until middle age, when heart attacks and strokes begin to occur."

To understand why the disease starts and how it progresses, Brown and colleagues looked to the metabolism of cholesterol and found answers. Most cholesterol is made in the liver and travels through the blood in tiny protein packages called "low density lippoproteins," or LDLs. Receptors inside each cell retrieve the LDLs from the cell surface and carry them inside to be broken down in a several-step process.

About one in 500 people in the world have a genetic defect that makes those receptors faulty, Brown said, and permits too much cholesterol to build up in the bloodstream. "Hypercholesterolemia," an illness that leads to arteriosclerosis, is one of the most common genetic diseases in the world, he said. During the past eight years, Brown and his team have defined gene mutations that deform the LDL receptor in persons who have the disease, have located the receptor within the cell, and are now trying to clone the genes in an effort to better understand and find new ways to treat arteriosclerosis.

The new tools of molecular and genetic medicine have found a niche in the study of normal processes as well as in the research of disease. Eric Kandel told the audience how his work with "aplysia," a variety of sea slug, is shedding light on the mechanisms of memory and learning.

"Some of us feel that the ultimate challenge facing biology is the neurobiology of mentation," Kandel said. "Can the complexity of behavior be explained by a simple grammar of biological rules?"

-more-

The sea slug has relatively few neurons that are large and much easier to study than the interlocking maze of cells that make up man's brain. The slug's behavioral repertoire is also quite simple, but the primitive behaviors, and ability to learn and remember are probably governed by the same molecular mechanisms as the more complicated processes seen in higher organisms, Kandel said.

Even remembering the name of an acquaintence probably causes semi-permanent changes in the junctions between nerve cells in the brain, he suggests.

Channels in the membrane of nerve cells open and close to permit electrically charged molecules to flow back and forth at the bid of an electrical signal initiated in the brain. Changes in the number of channels that open determine how much neurotransmitter—the chemical messenger between nerve cells—will be released.

Kandel and his associates have studied the sea slug's "gill withdrawal reflex," the tiny creature's response to being disturbed. In calm tidepools, a sudden change in water pressure signals that a predator may be nearby, and prompts the gill withdrawal reflex as a first step towards escape.

But when repeated stimulation with the same stimulus signals no ill effects, the sea slug grows accustomed, or "habituates" to the stimulus. Through experiments, Kandel has linked the habituation to a change in the number of specific ion channels open in the cell membrane. If the sea slug is then exposed to a new stimulus—such as a mild pinch—the configuration of open channels changes again, more transmitter is released, and the creature quickly withdraws his gill.

Neurobiologists see habituation and its sister phenomenon "sensitization" as building blocks of learning.

Other speakers at the symposium included Philip Leder, Harvard Medical School; Gerald Ruben, Carnegie Institution of Washington; and Leon Rosenberg, Yale University School of Medicine.

Paul Berg, Stanford's Nobel prize winning geneticist, called Friday's symposium a "treasure trove of scientific discovery." The conference will be held annually, Purpura said, to "memorialize life through the study of science" and to foster the translation of research advances in molecular and genetic medicine into revolutionary methods of disease diagnosis and treatment.

HEMATOLOGY SUPPORT GROUP FORMED

STANFORD—

How would you feel if your doctor told you you had leukemia? Or hemophilia? Whom would you talk to? How many of your friends and relatives understand what problems such diseases present?

These are just some of the reasons that a new patient support group has been formed at the Medical Center for patients treated in the hematology clinic with relatively rare diseases such as leukemia, multiple myeloma, polycythemia, or hemophilia.

The group enables patients with the same types of medical problems to share the feelings, frustrations, coping strategies and other concerns peculiar to this type of health problem. The support group meets each Wednesday from 10:30 a.m. until noon.

The group is run by Dr. John Ruark, a resident in psychiatry, and Phyllis Burton, R.N., B.S.N., a staff nurse in the hematology clinic. Also frequently present are Juanita Smith, M.S.W., and Kathleen O'Brien, M.S.W., both from the department of social services.

Patients are welcome to bring family members or friends to the support group, which meets in TF-122c of the Psychiatry Building at the medical center. Other health care staff are also encouraged to attend at any time.

For further information, call the hematology clinic at (415) 497-6961.

LIVING AND COPING AFTER MASTECTOMY

STANFORD—

To heal her scars is the goal of a mastectomy patient on the road to recovery.

Often overlooked, however, is the fact that these scars are more than skin-deep. The emotional recovery of a woman who's undergone a mastectomy is frequently harder to reach—and longer in coming—than her physical recovery.

"Women who've had mastectomies as long as 20 years ago still experience the same emotional stresses as those new to the situation," said Regina Kriss, Ph.D., and project director of postmastectomy group therapy in the department of psychiatry at Stanford. "It's clear that, contrary to what many women have traditionally been told, time alone will not help."

It was largely these considerations that led Kriss, a family therapist, to undertake a study of the role of therapy in helping women deal with their psychological reactions to breast loss.

Specifically, Kriss collaborated with Dr. Helena Kraemer, associate professor of pschiatry, to research the effects of group therapy on the sexual adjustment and self-image problems of postmastectomy women.

A panel of postmastectomy women, joining Kriss in a public lecture at the Medical Center last week, confirmed that the group setting had been particularly helpful. It provided the chance for each woman to hear her own emotions expressed and validated by others, and as one woman said, "to feel that she was probably not the worst off."

Sixty-two women entered Kriss' study groups, which began in 1979. Compared to women who had not had mastectomies, these women were less self-accepting, less sexually active, more dependent, and more self-sacrificing, she said. Both married and single women had experienced profound changes in their sexual interactions.

5-16-83

-more-

As demonstrated in "No Less a Woman," a dramatized documentary film made by Kriss and Marvin Silverman, professor of education at San Francisco State University, married women often found their husbands withdrawn and cold, unable to offer comfort or to express their own sorrow and fear; many single women, terrified of rejection, shrank away from establishing any relationships with men.

Kriss, who has herself had two mastectomies, explained, "Breasts are a symbol of femininity, of desirability. Without them, it seems that everything you can offer a man is gone. It isn't vanity—it's the loss of an essential part of your core of existence as a woman."

Says one woman in the film, "I feel like a fraud. On the outside I look fine, but I'm not a real woman on the inside. I can't stand even looking at myself in the mirror; how can I show anyone else?"

Kriss said that because of these feelings, and possibly also because of the anger they feel about what's happened to them, some postmastectomy women end up feeling asexual. Ironically, at the same time, they may feel a greater need for sex and a sexual relationship than ever before.

"Some women find it harder to make a sexual adjustment toward their husbands than toward other men, since with their husbands there's more a sense of sadness about their loss," said Kriss.

But one man in the audience commented, "Being a WWII veteran myself I've seen many people have to cope with physical mutilation. Twenty years ago it would have been harder I think, but now I just know I'd rather have my wife here than not. So I can look at those pictures of mastectomy scars, though it's hard, and I can tell my wife here in public that I hope to God it never happens to her, but it won't make a damn difference to me if it does."

Because the issue is so complicated, Kriss soon realized in her research that she had to include men. So she held separate and then couples group sessions. She also did this with the women's daughters, most of whom were frightened, realizing they were at higher risk for cancer.

"In both cases, I found that everyone was protecting everyone and not telling how they felt. Through the groups they were all able to open up more." She added, "This is a time for close communication within a family, and all family members, even sons, are affected."

(In the next step of her studies, Kriss plans a pilot study on family work through groups of mothers and daughters, in collaboration with Dr. Alice Lee, a psychiatrist in private practice and a clinical instructor in the department of psychiatry.)

-more-

During the study, the importance of early therapeutic intervention after mastectomy became increasingly obvious, said Kriss. Few doctors realize the trauma of the surgery, she said, or prepare their patients for its psychologic impact.

"Doctors don't know because their patients don't tell them. To be 'good' patients, women after mastectomy deny perfectly normal feelings. They have to take the responsibility for communicating their problems, and doctors have to listen."

One woman in the audience added, "If any doctor says, 'Never mind that, just trust me,' run away so fast that you can't see straight."

Kriss attested that the medical community is now becoming more aware and attuned to the special problems of mastectomy patients. In Hoover Pavilion at SUH, she said, women and their husbands are interviewed carefully on attitudes towards breasts and the possibility of breast loss.

One exercise of her therapy groups was for the women to go home and really look at their scars. At another session, the women decided to compare their scars. "That was so therapeutic," said one. "You could say to yourself, 'hey, it doesn't look so bad when you look at someone else.' "

Emotional recovery after mastectomy, said Kriss, is tied intrinsically to the medical experience of surgery followed by chemotherapy or radiation. "The whole thing is so traumatic because of its suddenness," she said. "One day you're OK, the next you're not. You're not prepared for it, it's not gradual like the aging process or the progression of chronic disease."

The question women later ask is, "My cancer's now cured, but what next? When do I start to feel like me again?"

Some women opt for reconstructive surgery as part of the recovery process or to make them more comfortable in their active, outdoor lifestyles. For others, going "under the knife" again is too frightening, or unnecessary.

But even those who've had successful reconstruction say it doesn't change the fear, or the knowledge that they've had cancer. It doesn't erase anything.

Neither does group therapy solve all the problems. But the most important thing every mastectomy patient must do, said Kriss, is admit to herself if she needs help coping and seek out a group that can help.

REAVEN AND PRINCE NAMED TO NEW ENDOWED CHAIRS

STANFORD—

Two new endowed professorships at Stanford University Medical School will sponsor faculty members conducting research in neurological sciences and in the mechanisms and treatment of diabetes, the University Board of Trustees announced Monday (May 9).

Gerald M. Reaven, a professor of medicine/gerontology and a leader in understanding the role insulin plays in diabetes, has been named the Nora Eccles Harrison Professor in Diabetes Research.

David A. Prince, professor and chairman of the department of neurology, has been named the Edward F. and Irene Thiele Pimley Professor in Neurology and the Neurological Sciences.

Reaven, 54, has focused his research on the physiology, biochemistry and mechanism of action of insulin in the human body. He helped verify that it is certain cells' insensitivity to insulin, rather than a lack of insulin, that is the source of the most common form of diabetes. Tracking the problem to a cellular level, the physician has actively pursued new treatments aimed at improving tissue sensitivity to insulin, and thus improving control of the disease.

The Harrison Professorship is the first in the diabetes field at Stanford, and was established to honor Nora Eccles Harrison, a noted artist in ceramics, and founder of the Nora Eccles Treadwell Foundation, which sponsors advances in medical research in the areas of cardiovascular diseases, arthritis, and diabetes in California and Utah.

The chair is the second professorship at Stanford endowed by a member of the Eccles family. In 1973, the Marriner S. Eccles Professorship was established in the Graduate School of Business in the name of Nora Eccles' eldest brother, an internationally known banker, business executive and former chairman of the board of governors of the Federal Reserve System.

Prince, 50, holder of the Pimley chair, studies the intricate communication between cells in the brain. He has made important contributions to understanding the development of electrical signals and abnormal discharges in nerve cells, as well as the ways transmitters—chemical messengers of the nervous system—affect nerve cell behavior.

Prince and his colleagues were the first to record from inside neurons of the human brain, and have pioneered techniques for keeping brain tissue alive in an artificial environment to study the cellular abnormalities that can underlie neurological disorders.

Irene Thiele Pimley, a long time San Francisco resident and patron of oriental art, was ill for many years with Parkinson's disease before her death in 1982. Her bequest to Stanford of more than $3 million for basic research into the causes and cures of Parkinson's and related neurological disorders reflected the interest she developed in the scientific background of the disease, her family said.

Pimley lived in China for many years with her husband, Edward, as a result of his business interests there. He was one of the founders of the American International Group, a marine and business insurance fund that operates internationally.

CHAS PROJECT DIRECTOR NAMED

STANFORD—

Mr. Langston G. Trigg, Jr. has been named project director for the New Children's Hospital at Stanford (CHAS), announced Dr. Lawrence G. Crowley, chairman of the Board of Directors.

Trigg has been assistant director of facilities/projects of Stanford University Medical Center since 1980. He will assume his new position on June 6, 1983.

As project director, Trigg will be responsible for overseeing the organization of planning and construction of the new children's hospital at the Medical Center. He will report directly to the chairman of the Board.

The boards of directors of Stanford University Hosptial (SUH) and CHAS agreed last summer to consolidate the pediatric facilities of both institutions. The new hospital— to be built at an estimated cost of $40 million—will be physically attached to SUH. It will consolidate the 60 beds at CHAS and the 44 pediatric acute medical-surgical and pediatric intensive care beds at SUH. It will also house the Stanford-Children's Ambulatory Care Center, which provides 27 separate clinic services. It will continue to provide inpatient services in the 15 specialties now offered by both hospitals.

Prior to coming to SUH, Trigg was facilities planner and project manager at Children's Hospital Medical Center in Oakland, where he headed up a $36 million new building project.

He received his master's degree in architecture from University of California, Berkeley, in 1975.

DIGITAL RADIOGRAPHY: 'THE WAVE OF THE FUTURE'

STANFORD—

An extension of a standard angiogram may provide more diagnostic information—while being less expensive, quicker, and more comfortable for patients—by incorporating modern computer technology, according to researchers at Stanford University Medical Center.

"Digital radiography is the wave of the future," said Dr. Diana Guthaner, assistant professor of radiology, who is researching its clinical applications. Still not widely available, the procedure works by digitizing the information—converting it to computer language. In many situations, this allows physicians to get a better image than with a standard angiogram, which gives a picture of the body's vascular system by using X-rays.

More specifically, digital fluoroscopy is being used instead of more invasive angiograms to screen various diseases of the blood vessels, and determine heart function and blood flow. It is also being used to supplement angiograms in order to get the most out of the information obtained.

With standard angiograms, a catheter—a long tube thinner than a drinking straw—is threaded into the blood vessel physicians want to observe. An iodine contrast substance is injected through the catheter. The contrast blocks the X-rays from going through the vessel onto the film. Thus, the vessel appears white on the film, while everything else not blocked by the contrast appears black.

Piercing the skin with the catheter in order to thread it to the specific vessel is painful for the patients, Guthaner said. The iodine can be irritating, she added, which also causes pain. Many patients with heart or kidney failure cannot handle the large amounts of iodine necessary in routine angiograms. The substance makes the body retain water, she explained, which such patients cannot tolerate.

Digital fluoroscopy, on the other hand, is "virtually non-invasive and non-traumatic," Guthaner said. As a screening method, the iodine is injected into the veins rather than the arteries. It dissolves in the body's blood quicker. Therefore, its concentration in a specific vessel is lessened, which decreases the pain.

The procedure is quicker as well, she added. Following routine angiograms, the patient is required to stay in the hospital for at least six hours, which usually ends up being overnight. Digital fluoroscopy, however, is done on an outpatient basis, thereby cutting costs.

Rather than looking at an X-ray, physicians call up an image on the computer screen. This image can be enhanced by subtraction techniques, through which everything but the vessel in question is eliminated from the screen.

-more-

There are limitations to the procedure, however. Often the image is not quite clear, Guthaner said, because it can be obscured by any patient motion. And if the vessels overlap each other, she continued, the procedure is not effective.

But, she added, many patients who would forgo an angiogram because of its invasiveness will agree to digital fluoroscopy screening. This gives physicians the chance to diagnose disorders of the vascular system early on.

Digital fluoroscopy can be incorporated in standard angiograms, Guthaner said, providing more information without using more contrast.

Potential clinical applications, she continued, include determining what type of therapeutic intervention to use, aortic disease, patency of coronary bypass grafts, cardiac function, and as a follow-up for vascular surgery.

LECTURESHIP NAMED FOR PROFESSOR EMERITUS

STANFORD—

The establishment of the David Glick Lecture, to be given at the Congresses of the International Federation of Societies for Histochemistry and Cytochemistry, has been announced by Dr. Sidney Goldfischer, president of The Histochemical Society.

Glick is a Stanford professor of pathology emeritus, now active in the department of radiology's Cancer Biology Research Laboratory. He was one of the founders of The Histochemical Society and served twice as its president. He was president from 1972-76 of the International Committee for Histochemistry and Cytochemistry, now the International Federation named above.

Among his distinctions Glick has an honorary LL.D. degree from the University of Glasgow, Scotland. He is an honorary member of The Histochemical Society (U.S.), Finnish Histochemical Society, and the Royal Danish Academy of Sciences.

He was given the Van Slyke Medal and Award (1977) and the Ames Award (1980) by the American Association of Clinical Chemistry, for his basic research applicable to this field.

Glick earned his B.S. in chemistry at the University of Pittsburgh in 1929, and his Ph.D. in biochemistry there in 1932. After an already extensive and varied professional career, he joined the Stanford Medical School faculty in 1961.

He has served on several scientific journal editorial boards, and has published widely.

The David Glick Lecture is to be given every four years by an outstanding histochemist or cytochemist selected by the officers of the International Federation. Glick has been invited to give the first Lecture at the next Congress in Helsinki, August 5-11, 1984.

UPCOMING LECTURE: SEXUAL AND EMOTIONAL PROBLEMS POST-MASTECTOMY

STANFORD—

The film "No Less a Woman," on self-image and sexuality after mastectomy, will be the focus of the next public lecture in a series sponsored by the Friends of Psychiatry and Behavioral Sciences at Stanford.

Before the film, speaker Regina Kriss, Ph.D., family therapist and project director of post-mastectomy group therapy in the department of psychiatry, will describe her research on the effects of group therapy on breast loss and sexual adjustment of post-mastectomy women.

The lecture will take place 8 p.m., Thursday, May 12 in the Sherman Fairchild Auditorium, and will include a panel of women who have participated in post-mastectomy group therapy. They will discuss and answer questions about their experiences.

In 23 minutes, the dramatized documentary "No Less a Woman" will reveal how group therapy helps women deal with the emotional problems so common after mastectomy.

The outgrowth of a collaboration between Kriss and Marvin Silverman, professor of filmmaking at San Francisco State University, the film is based on the experiences of the women in Kriss' study.

"The film has tremendous power," said Kriss. "It leads viewers to experience for themselves what is happening in these women's lives. Because it communicates problems that are hard to describe, it has turned out to be a valuable teaching tool."

The film treats the reactions of both married and unmarried post-mastectomy women, both groups of whom experience profound changes in their sexual interactions, said Kriss, who has herself had two mastectomies.

Admission to the evening presentation is free, and there are no reserved seats. Dr. Thomas Gonda, professor and chairman of psychiatry and behavioral sciences, will serve as moderator.

For further information or to get on the Friends of Psychiatry and Behavioral Sciences mailing list, contact Karen Sortino at (415) 497-6376.

COMPANY LICENSES GENE CLONE PATENT

STANFORD—

Creative BioMolecules Inc., of Brisbane, Calif., has licensed rights to the DNA cloning patent held by Stanford University and the University of California at San Francisco, Stanford announced Monday (May 2).

John Callahan, president of the 1-1/2-year-old biotechnology company, said the patent was needed to perform quality control functions on chemically synthesized genes, including a product which offers the eventual possibility of helping persons with growth deficiencies.

The patent issued Dec. 2, 1980 covers the basic techniques of DNA cloning—often called gene splicing—which were developed by Stanley W. Cohen, professor of genetics at Stanford; and Herbert W. Boyer, professor of biochemistry at UCSF.

Seventy-four companies have taken out licenses, and current license holders total 68, said Katharine Ku, who administers the DNA cloning license for Stanford's Office of Technology Licensing.

Ku said several companies have dropped the license because they were no longer planning to use the technology, while other companies dropped out when they were acquired by other firms already holding a license.

The patent grants nonexclusive rights to this patent and a pending U.S. patent application which covers "products"of the technique. Ku said Stanford has not been actively soliciting new licensees actively until the outcome of the pending application is known.

Net proceeds from the licensing are split evenly between Stanford and UC and used to support research and education. To date, more than $2 million has been derived in licensing fees, Ku said.

One consumer health product, insulin, has been made and marketed from bioengineeering techniques based on the Stanford-UC patent. Other products are being made and sold in research, said Ku.

Creative BioMolecules, which has laboratories in the Boston and San Francisco areas, recently announced the availability of one such research product, its chemically synthesized gene for human growth hormone-releasing factor (hpGRF).

Callahan said the hpGRF gene will be offered for sale on a nonexclusive basis to any university or industrial group interested in the study or production of hpGRF.

The gene is a tool which a company eventually might use to manufacture medication which will trigger the release of a patient's natural growth hormone. Callahan estimated several years would elapse before any product could be available for widespread clinical use.

Creative BioMolecules specializes in nucleic acid and protein chemistries and their applications to the field of biotechnology.

AIDS: ANSWERS TO COMMON QUESTIONS

STANFORD—

Reporters/editors:

Acquired immunodeficiency syndrome (AIDS) has gained widespread, and often alarming publicity recently. Dr. Thomas Merigan, chairman of the department of infectious disease, and Carol Oakes, R.N., assistant director of care review/risk management for the Stanford University Hospital, helped to prepare the following column to help the public separate fact from fiction on current understanding of the syndrome and how it is spread. You should feel free to use it as background, reprint it, or excerpt any portion in your ongoing coverage of AIDS.

What is AIDS?

Acquired immunodeficiency syndrome strikes the immune system, zeroing in on two types of T-lymphocytes (T-cells), a class of white blood cells crucial to the human body's ability to battle infection. Helper T-cells, the generals of the immune system that regulate the army of cells that mobilize each time a foreign substance or organism enters the body, usually are found twice as frequently as suppressor T-cells in a healthy person. But in a patient with AIDS, suppressor cells, which normally keep the immune system from running amok, outnumber helper cells. In addition, the overall number of T-cells is reduced. As a result, the AIDS patient's immune system is stripped, leaving him vulnerable to infections that a healthy person can easily thwart. Incubation time between the exposure to AIDS and the onset of symptoms has been between six and 18 months in some cases.

What are some of the diseases affecting AIDS patients?

About 90 percent of the cases studied have had one or both of two rare diseases: a usually rare type of cancer known as Kaposi's sarcoma, and *Pneumocytosis carinii*, a parasitic infection of the lungs. Other infections that have afflicted AIDS patients include yeast infections, cytomegalovirus (CMV), herpes, and toxoplasmosis.

How serious is AIDS?

AIDS has a high mortality rate, ranging from 20 to 70 percent, depending on the specific infection. Patients don't die from AIDS; they die from the serious infections that develop because AIDS has stripped away most of their natural immunity to disease. The Centers for Disease Control report that, as yet, they know of no AIDS patients who have regained immunity, so that even if a specific bout of illness can be curbed, repeat infections are likely.

Is AIDS a new disease?

Yes, apparently so. Careful studies show no clear evidence of AIDS before 1979. The origins of the disease are still unclear, although many scientists now believe that AIDS is caused by an unidentified virus that specifically attacks lymphocytes. Such a virus might be a mutated form of a more common human or animal virus, and probably interacts with a number of other factors to cause disease.

Are there any symptoms characteristic of AIDS?

There are no clear cut symptoms to indicate a loss of immunity, but many patients with AIDS complain of fever, a loss of appetite, sudden weight loss, extreme fatigue and enlargement of the lymph glands. These symptoms often develop over a period of several months before becoming severe enough to be markers for specific diseases. Early symptoms of Kaposi's sarcoma include brown or blue-violet spots that can appear anywhere on the skin or in the mouth. As the disease progresses, the spots grow larger and may become open sores. Pneumocystis pneumonia triggers symptoms similar to any other form of severe pneumonia, highlighted by fever and difficulty in breathing.

Is there a laboratory test for AIDS?

There is no specific laboratory test that can diagnose AIDS patients. However, 95 percent of AIDS patients show an identifiable change in the numbers of different types of cells in their immune system. This difference is currently being used at the Stanford Medical School Blood Bank as an indicator of donated blood that might inadvertantly have come from a person with AIDS. The blood screening method is not perfect. Sometimes a harmless viral infection can initiate the same change in the blood cells, and some healthy people contain the unusual characteristic naturally in their blood. But physicians at Stanford's blood bank feel that the very small amount of blood lost because it was mistakenly thought to have come from a person with AIDS is worth the extra protection it affords blood recipients. Researchers around the world are currently seeking a less expensive, more effective method of screening blood for AIDS.

Who is at risk of contracting AIDS?

Currently, the people known to be at highest risk for infection are homosexual men with many partners (75 percent of the cases), intravenous drug abusers, hemophiliacs and Haitians. The link between the first three groups appears to be exposure to blood or blood products. Whatever spreads the disease seems to be present in blood and semen, and perhaps mucus and saliva. Airborn spread, through a cough or a sneeze, and spread through casual contact with a person with AIDS do not seem likely means of disease transmission.

-more-

Needles shared by drug users provide an obvious route of transmission. Hemophiliacs who lack a vital clotting factor in their blood often receive a transfused concentrate of the factor to stop their bleeding. Such a factor, which occurs naturally in minute quantities in blood plasma, may be pooled from hundreds of donors for one transfusion. The mode of transfer of disease among homosexuals is unknown, although the small amount of bleeding from the lining of the anus that can occur during anal intercourse has been suggested as a likely possibility. The Haitian victims, as yet, do not fit the blood-transmission pattern.

A few people who don't fall into the identified high risk groups have contracted the disease, but nearly all seem to have had some close connection to one of these groups. The detection of AIDS in a few women and babies, for example, does not mean that all mothers and babies are at risk. The women who developed the syndrome had sexual partners who had AIDS. Except for the few children who have acquired the illness through blood transfusion, babies who contracted the disease were born to women who probably had AIDS themselves and may have transmitted the illness during pregnancy or while giving birth.

Are hospital employees at risk for contracting AIDS?

To date, no cases of AIDS have been reported among those caring for the slightly more than 1500 AIDS patients around the world. Researchers studying the disease recommend that hospital personnel take the same precautions when caring for AIDS patients as those used for patients infected with hepatitis B virus, which seems to follow the same pattern of transmission as AIDS.

Guidelines from the Centers for Disease Control in Atlanta, Georgia, suggest that "patient-care and laboratory personnel should take precautions to avoid direct contact of skin and mucous membranes with blood, blood products, excretions, secretions, and tissues of persons judged likely to have AIDS."

A private room, disposable dishes, careful bagging of linen and trash as well as the use of gowns, gloves and sometimes masks (depending upon the specific infection) are standard procedure in caring for these patients at Stanford. Members of the health care team are advised to use special care while drawing blood and disposing of needles to avoid pricking themselves. Any specimens of blood or body secretions sent from AIDS patients to the hospital laboratories are labeled as having come from patients in isolation. Laboratory workers should avoid getting such specimens on skin, or mucus membranes.

STANFORD ONCOLOGIST NAMED AMERICAN CANCER SOCIETY PROFESSOR

STANFORD—

Dr. Saul A. Rosenberg, professor of medicine and radiology at Stanford University School of Medicine, has been awarded a Professorship in Clinical Oncology by the California Division of the American Cancer Society.

Rosenberg is the second scientist in California to receive the professorship. The Society is funding only 17 others in the country.

The professorship was established in 1971 to allow receipients to improve and expand cancer teaching programs and cancer patient care at their institutions.

"It is an honor to be selected from among the candidates throughout the state," Rosenberg said. "It reflects not only on my work, but on the excellence of the institution."

Rosenberg will receive $125,000 over the next five years. The funding, he said, will facilitate the department of medicine's and Medical School's search for another cancer investigator, which will allow Rosenberg more time to become more involved with cancer-related activities at the Medical Center and within the region.

"We hope to be able to collaborate further in our multidisciplinary approach to cancer teaching, research, and patient care," Rosenberg said.

Rosenberg has recieved international acclaim for his research on Hodgkin's disease. He and Dr. Henry S. Kaplan, D'Ambrogio Professor of Radiology, have made dramatic advances in the diagnoses and treatment of the disease, which have led to better than 80 percent survival at five years for all stages of the disease. Seventy-five percent of the patients are permanently cured, according to published figures.

Rosenberg is chief of the Division of Oncology at Stanford, having been among those who spearheaded the development of oncology as a specialty of internal medicine. He is also director of the Debbie Probst Oncology Day Care Center, a treatment center for cancer patients.

He has received the Henry J. Kaiser Award for excellence in Teaching, and was the first recipient of the Arthur Bloomfield Award for Excellence in Teaching in Clinical Medicine.

NEW STANFORD MEDICAL ALUMNI ASSOCIATION OFFICERS

STANFORD—

Dr. Donald Prolo, a San Jose neurosurgeon, is the new president of the Stanford Medical Alumni Association, and Dr. James Gordon Holmes, a Berkeley surgeon, is the president-elect for the 1983-84 year.

Holmes' election was announced at the recent alumni reunion held at the Medical School, which coincides with the organization's annual meeting.

Prolo, '61, has served on the association's board of governors, and is regional chairman for the south peninsula chapter of the Medical Fund, which provides financial aid for medical students.

He succeeds Roy Cohn, '33, emeritus professor of surgery at Stanford.

Holmes, '47, has been the association representative to the Medical School faculty senate. He has been on the board of governors, as well as other association committees. He also is a professor in health sciences and medical education at University of California, Berkeley.

BASIC RESEARCH IN BLOOD CLOTTING SPAWNS NEW CLINICAL APPLICATIONS

STANFORD—

A potent anti-clotting factor discovered in recent years in the cells that line blood vessel walls is already showing important clinical use in open heart surgery, hemodialysis and in stroke victims, a British Nobel laureate told an international conference at Stanford University Medical Center on Wednesday (June 22).

"Prostacyclin," a hormone-like substance discovered almost by accident in 1976, is an excellent example of how often basic research bears clinical fruit, said John Vane, the pharmacologist from Wellcome Laboratory, Kent, England who shared the 1982 Nobel prize in medicine.

"The medicines of tomorrow will be based on the discoveries made right now," Vane told a meeting of 150 pharmacologists, chemists and biologists gathered at the second annual symposium on the biochemical basis of drug action.

Vane won the 1982 prize for his role in deciphering the mode of action of aspirin and similar drugs as they inhibit a family of chemical messengers called "prostaglandins."

Originally thought, 50 years ago, to be manufactured only by the prostate gland, prostaglandins are now known to be produced by nearly every type of cell in the human body and to play a regulatory role in activities as far flung as protection against ulcers, the contraction of the uterus during labor and the dilation of blood vessels.

Vane's current work focuses on prostacyclin, a highly unstable derivative of the prostaglandins, that is produced primarily by cells that line the walls of blood vessels, and is a potent inhibitor of blood clotting. Vane and colleagues have used the substance to unravel the mystery of how platelets—bandaids of the blood vessel network—"know" when to begin formation of a blood clot and when to sail through the vessels without clinging to vessel walls.

-more-

6-24-83

"For years, people said that the reason platelets didn't stick to the walls of healthy arteries was because of the smooth, slippery nature of the blood vessels," said Vane. "But we now believe that it's the production of prostacyclin that helps keep the platelets from sticking."

While cells of the blood vessel produce prostacyclin, platelets themselves produce "thromboxane," a chemical similar in structure to prostacyclin but opposite in function. Together the two chemicals help maintain a delicate balance, in ways still not understood, to make sure blood clots only when necessary.

Now, more and more physicians are taking advantage of this balance to fine tune the control of unwanted bleeding, said Vane.

During procedures such as open heart surgery or hemodialysis, when blood is circulated outside the body through synthetic tubing, the risk of clotting would be great, Vane said, were it not for anti-clotting additives. Most often heparin, another anti-coagulant, is trickled into the blood, but can lead to unstoppable bleeding in some patients. In contrast, prostacyclin only prevents clots temporarily, he said, and is a superior alternative for patients, such as hemodialysis patients with bleeding ulcers, for whom heparin poses a risk.

Still fairly difficult to store because of its instability, prostacyclin will probably not replace heparin, said Vane, but could be used supplementally to reduce the doses of heparin needed.

Physicians in the United States and Europe are currently exploring other uses for prostacyclin, Vane said, including limiting the damage done by strokes, and in helping prevent and dissolve blood clots in patients with peripheral vascular disease.

"We only know about a tenth as much now about the fundamental processes as we shall know in a year's time," said Vane. "There are plenty of ideas and plenty of things left to discover. The trick is in finding the path from one to the other."

HYPNOSIS EXPLORED AS CURE FOR ULCERS

STANFORD—

A gastroenterologist and a psychiatrist at Stanford University Medical Center are looking for volunteers to learn whether ulcers eventually may be hypnotized away.

"We're a long way from having any definite answers, but we have at least an indication that hypnosis might lower stomach acidity for some people," said Kenneth Klein, clinical instructor of medicine and a specialist in diseases of the stomach and intestines.

"Since lowering stomach acidity has been shown to aid in ulcer healing, there is a possibility that hypnosis exercises might someday be a useful substitute in some cases for medication in the treatment of ulcers," he added.

Klein is working with David Spiegel, associate professor of psychiatry, who has studied the medical uses of hypnosis.

Klein cautioned that his study is intended only to give an indication—not proof—of whether hypnosis might be useful as an ulcer treatment. If the technique is eventually found to heal ulcers, it would only be helpful for the 25 to 50 percent of the population who are good hypnotic subjects, Klein said.

Volunteers for the current study should be healthy adults who will be tested to determine whether they are hypnotizable. (Former ulcer patients are acceptable if they are showing no current symptoms, Klein said). Their stomach acidity will be analyzed using a tube inserted into the stomach through their nose after a local anesthetic is applied. Then a hormone, pentagastrin, will be administered to stimulate acid production, and stomach acidity will be compared with the first test.

A week later, the volunteers will return to the Medical Center and their stomach acidity will be reanalyzed. But this time, half the volunteers—about five persons—will be hypnotized and given coaching and suggestions intended to lower their stomach acidity. About five other volunteers will repeat, again without hypnosis, the test taken earlier to serve as controls.

So far, one volunteer has completed the procedure, and his stomach acidity declined markedly under hypnosis, Klein said.

"Hypnotism has been viewed with some skepticism by the medical community, but after 10 years of experience with it, I am quite convinced of its ability to dramatically effect many physiological processes. I'm most anxious to study its potential effects in my own specialty, gastroenterology.

-more-

6/20/83

The physician added that the current study could begin to offer some scientific answers about what mechanisms trigger gastric acid production.

Klein explained:

"If a person can control acid production through the mental concentration or trancelike state which hypnosis brings, we might be able to learn more about how acid production is triggered. We don't know, for example, the relative importance of the central nervous system, the vagus nerve and various hormones in causing gastric acid secretion. If we can prove that hypnosis—which presumably acts primarily through the central nervous system—can moderate acid production, we can begin to explore the intervening pathways."

Klein said the medication most often prescribed to relieve ulcers works by lowering stomach acidity, even though acidity might not be the only cause of ulcers.

If hypnosis is effective, some patients might be able to avoid taking any medication for their ulcers, Klein said.

Patients, he said, could be taught to self-induce a hypnotic trance several times daily at key times when controlling acid production is crucial. This would eventually be less expensive than drugs and would bypass the potential side effects which are always present when drugs are given.

Klein explained that hypnosis was a state of intense concentration, not relaxation, so that techniques of relaxation cannot be used as substitutes for hypnosis. He aaded that the ability to be hypnotized appears to be innate and cannot be acquired.

"Easily hypnotizable people don't appear to show any consistently common qualities, except perhaps that they have the ability to concentrate intensely and have long attention spans, They are often the kinds of people who become so engrossed in reading material that they become totally unaware of what is happening around them.

"We will be giving our volunteers a test which will indicate their ability to be hypnotized. The test involves answering some questions, and measuring how they respond to a brief hypnotic session," the researcher said.

Persons interested in participating in the study may telephone Klein at (415) 497-5488.

Persons who complete the study will be paid $40. Each of two sessions will take about 2 1/2 hours, he said.

Klein said there were no risks from hypnosis. The gastric tube may be uncomfortable for some participants and cause a minor sore throat, or gagging as the tube is inserted.

The hormone to stimulate acid production may cause brief nausea or flushing and rapid heart rate, while a very rare subject might suffer an allergic reaction, Klein said.

VOLUNTEERS NEEDED FOR BLOOD PRESSURE AND ALCOHOL STUDY

STANFORD—

Volunteers are needed to participate in a study aiming to clarify the relationship between blood pressure and moderate alcohol intake.

Researchers based in the Stanford Heart Disease Prevention Program (SHDPP) are seeking 40 to 60 healthy, non-smoking men, over 30 years old, who drink one to four alcoholic beverages per day. The study will run from July 7 through the end of August.

Participants will be asked to abstain from drinking for a three-week period, and to record their alcohol intake throughout the rest of the study period. They will make short weekly visits to the SHDPP's clinical facility on Welch Road, Palo Alto, to have their blood pressure, weight and height measured. Volunteers are expected to gain a better awareness of their own health status.

Principal investigator for this new study is Dr. Stephen Fortmann, physician specialist at the SHDPP. For further information or to volunteer, call (415) 497-5046, from 1 to 5 p.m. weekdays.

HIGH-RISK BABIES AND MOMS: NUTRITIONAL CONSIDERATIONS

Editors, City Desks: Members of the news media are invited to attend and/or cover any portions of this three-day conference. **Note underlined correction.**

STANFORD—

A conference on the nutritional care of high-risk obstetrical patients and high-risk infants will be held in Fairchild Auditorium and some M classrooms of Stanford Medical Center Wednesday through Friday, June 15—17.

The conference is oriented to nutritionists, nurses, obstetricians, pharmacists, neonatologists and other physicians who are involved in the care of these patients.

It is intended to increase the knowledge of health care personnel of the nutritional needs of these women during pregnancy and lactation as well as of the immature and ill newborn, and the difficulties encountered in attempting to provide adequate caloric and fluid intake for these infants.

Both theoretical and practical points will be raised through the use of lectures, round tables, and workshops.

Sponsored by the departments of pediatrics, obstetrics and gynecology, and dietetics, the program will include such topics as "New and Future Issues in Perinatal Nutrition," "Severe Preeclampsia: The Highest Risk Pregnancy," "Specific Nutritional Deficiencies and Excesses; Impact on Pregnancy Course and Outcome," "Exercise During Pregnancy," "Ethical Dilemmas in Perinatology," and many more.

The faculty includes many Stanford physicians and other professionals involved with these issues, as well as several knowledgeable guest speakers from around the country. The program directors are Dr. Philip Sunshine, professor of pediatrics and director of newborn nurseries at SUH; and Dr. John Kerner, Jr., director of pediatric gastroenterology.

A fee is charged (*except to members of the news media*), and continuing education credit is available. For further details on the conference and enrollment information, call (415) 497-5711.

NIH GRANT TO HELP STEER YOUNG DOCTORS TOWARD ACADEMIA

STANFORD—

A training grant renewal from the National Institutes of Health for approximately $900,000 over five years has been awarded to Dr. Eugene Robin, professor of medicine and physiology at Stanford University School of Medicine.

The grant, by encompassing some new features, will allow an expansion of the pulmonary training program. Designed by Robin, who has overseen the program for several years, the new approach is hoped to attract more aspiring and fledgling M.D.s to the research labs.

"Many fewer young physicians are entering academia and biomedical research today than as recently as five years ago," Robin said, adding that this is observed particularly in clinical areas, and even more specifically in certain high-technology areas where there is now a substantial oversupply of clinicians.

The reasons for this phenomenon and how to overcome it have become the focus of much of Robin's attention.

"The progressive decline of M.D. academicians is a widely recognized, national problem," he said. "But it is particularly pertinent at a place like Stanford, which—with remarkable academic resources—is equipped to be in the forefront of research and teaching."

Moreover, he added, there is little need for Stanford to train pulmonary clinical specialists, of whom there is an abundance, and who are now needed "probably only on a replacement basis."

Until about five years ago, Robin said, 80 to 90 percent of young physicians trained in the pulmonary division under the now 21-year-old NIH grant went on to pursue careers in research. But of the latest group of trainees, only 30 percent went that route.

"The reasons are varied," he remarked. "There are changing values which view the independence of a clinician's life as happier than the stresses of an academic life. A career in research is very demanding. Economic factors probably play a role too."

The program revisions involve a two-pronged approach which recognizes that medical education must be flexible enough to meet new challenges as they arise.

First, the program will offer a new form of training to medical students—a marriage of their clinical and basic science preparation. "Under the conventional method, bench research is divorced from the student's clinical training," explained Robin. "We want to connect the two, to show the connections more clearly.

6-14-83

-more-

"Our students will be trained under the same circumstances in which they'll work in clinical departments," he added. The hope here, he said, is to make an impact on students while they're still at an early, formative stage in their training, before they become M.D.s.

"I'm not saying Stanford shouldn't emphasize the teaching of clinical medicine," said Robin. "However, we should be turning out students who are trained to think critically and know how to apply the best in medical science to patient care."

Two medical students, Mark Morin and Jesse Dodd, have already taken part in a trial of this approach, he said. The time spent in the training program is not a part of the regular studies leading to an M.D. degree, and is not eligible for credit towards the degree. However, these students have the opportunity to take a graduate degree, either M.S. or Ph.D., in physiology.

The second feature of Robin's plan involves young physicians who have finished their clinical training as pulmonary specialists, and who will be offered two years of further academic pursuit. "We've seen some people become interested at this stage, when they see that a purely clinical life is not enough to satisfy them," he said.

"The goal is to have 100 percent of the trainees under this program wind up in academic life. Of course with the medical students, this may not and need not be in the pulmonary field."

Robin said for the upcoming year there is still room for two medical students and three M.D.s under the new program.

The grant renewal, which takes effect July 1, also includes conventional training of pre- and postdoctoral Ph.D. candidates, and postdoctoral M.D.s without prior pulmonary training. The latter group will now also be offered research experience following clinical training in the pulmonary field.

"Hopefully, the more trainees we expose to the rewards of academia, the more will choose it as the base for their careers," Robin said.

Robin is acting chairman of the physiology department. The research basis of the training program involves the cellular pathophysiology of respiratory failure, and lung structure and function. Training is offered in molecular genetics and in heart-lung transplantation physiology, as well.

The intent is to meet the needs of trainees from many different backgrounds, by including contributions from Stanford faculty cellular physiologists, biochemists, pathologists, cardiovascular surgeons, clinical pharmacologists, infectious disease specialists, psychiatrists, and pulmonary disease specialists.

The training faculty, besides Robin, includes Drs. Lawrence Simon, James Theodore, Kay Ptashne, and Antonius Van Kessel.

"The idea is to use our new training program as a model for responding to a national problem," Robin concluded. "It may represent the type of innovative role that academic medical centers can assume in training the scientists of the future."

NIH GRANTS AWARDED FOR BIOMEDICAL RESEARCH

Details follow asterisks.

STANFORD—

The genetics of immune diseases, oxygen boosters for the blood, and the ways certain chemicals are linked to cancer of the larynx are among the newly funded research topics to be explored by five young scientists at the Stanford University School of Medicine.

Each researcher was awarded a $5,000 allocation in May from the Biomedical Research Support Grant, provided twice each year by the National Institutes of Health, and administered by a Stanford faculty committee.

The grant is designed to help young scientists establish research programs in areas of basic and clinical research.

The five assistant professors awarded one-year grants are: Mark Davis (medical microbiology), Martin Hopp (otolaryngology/surgery), Susan Perrine (pediatrics), J.H. Pate Skene (neurobiology), and Michael Weinrich (neurology).

* * * * *

Davis will use his grant to explore the ways certain severe immune diseases present from birth may arise from a specific deletion in the genetic code of a developing embryo. Scientists know that human illnesses such as severe combined immunodeficiency disease or Wiskott-Aldrich syndrome have a genetic component, but until now, no one has been able to determine exactly which genes are responsible for the illnesses, Davis said.

Hemoglobin F, a special variety of the oxygen carrying component of blood, is the research focus of Perrine. Normally, Hemoglobin F is produced primarily before birth, to be replaced by Hemoglobin A in the growing child and adult. Many diseases of the red blood cell, such as sickle cell anemia, might be ameliorated if Hemoglobin F production could be "switched on" again after birth, Perrine said. She is investigating the way 5-Azacytidine, a drug used to fight cancer, coincidentally activates some genes that are normally suppressed, and leads to a boost in Hemoglobin F.

Hopp is using chemical tools to probe cells of the larynx in his efforts to better understand how a cancer-causing agent is activated inside the cell. Though larynx cancer is strongly correlated with heavy smoking and drinking habits and occupational exposure to certain hazards, the chemicals themselves are not carcinogenic, said Hopp, but must be broken down by enzymes in the cell to trigger cancer.

Susceptibility to larynx cancer in some individuals may be linked to elevated levels of such enzymes, said Hopp.

Weinrich is studying vestibulospinal reflexes in primates—the network of neurons that enable animals (and humans) to use information from the outside world to maintain posture and balance in a moving world.

Skene is investigating the genes that seem to regulate the growth and regeneration of some nerve cells.

GOODKIND PROMOTED TO NEWS DIRECTOR

STANFORD—

Mike Goodkind has been appointed news director in the Medical Center's office of communications effective June 1, announced Spyros Andreopoulos, director.

In his new capacity, Goodkind is responsible for the day-to-day news activities of the medical center. He coordinates news assignments, and acts as the spokesperson for SUMC.

The delegation of this responsibility was necessitated, Andreopoulos said, by his own recently expanded role as director of the Office of Communications.

With Stanford since May 1981, Goodkind will continue to edit the *Medical Staff Update*, and assist Andreopoulos in development of the SUMC publications program.

His professional experiences include work for newspapers in Vermont, Arizona, and California, and as a reporter for the Associated Press in Los Angeles from 1971 to 1979.

A graduate of Dartmouth, Goodkind has served in Africa with the Peace Corps, and with the Army in Vietnam.

INTERNATIONAL MEETING ON BIOCHEMICAL BASIS OF DRUG ACTION AT STANFORD JUNE 20-24

Science writers/editors:

John Vane, the British pharmacologist who shared the 1982 Nobel prize in medicine, will highlight his most recent work in the study of prostaglandins during a week-long international symposium to be held June 20-24 at Stanford University School of Medicine.

Reporters are invited to attend any and all sessions of the "Second International Symposium on the Biochemical Basis of Drug Action."

Prostaglandins and their sister compounds leukotrienes are hormone-like substances found to play a powerful role in maladies as wide ranging as ulcers, rheumatoid arthritis and high blood pressure.

In addition to Vane's work which explores the mode of action of aspirin and other anti-inflammatory drugs, topics will include research on opiate receptors in the brain, new methods of disarming parasites through molecular engineering, and current research to track the paths of environmental carcinogens as they make their way into cells and lead to cancer by fouling-up genetic machinery.

Copies of the program can be obtained by calling the Medical Center News Bureau at (415) 497-6911. Reporters interested in attending any part of the meeting are urged to notify the News Bureau as soon as possible to aid in the scheduling of a press briefing.

Conferees will be charged a registration fee, but reporters are invited to attend all sessions free of charge.

TOXOPLASMOSIS BECOMES LETHAL IN AIDS VICTIMS

STANFORD—

A common parasite that lingers harmlessly in humans has joined a list of maladies which turn deadly in persons suffering from Acquired Immune Deficiency Syndrome (AIDS), scientists say.

About 60 cases of acute toxoplasmic encephalitis, a potentially fatal brain disease, have been found to be caused by the parasite Toxoplasma gondii since July 1981, "and our research shows that this occurred in patients suffering from AIDS," said Benjamin J. Luft, a medical instructor at Stanford and a research scientist at the Research Institute at the Palo Alto Medical Foundation (PAMF).

Luft and two colleagues—Jack S. Remington, professor of infectious diseases at Stanford and director of the department of immunology and infectious diseases at PAMF; and Frances Conley, professor of neurosurgery at Stanford—published findings linking toxoplasmosis and AIDS in the April 9, 1983 *Lancet*, a British medical publication.

The article details 10 of the 60 cases of central nervous system toxoplasmosis (encephalitis) that have occurred throughout the United States and Western Europe. It focuses mainly on the linkage of toxoplasmosis to encephalitis and an "epidemic" increase in toxplasmic encephalitis in the past two years. Acquired immunodeficiency contributed to to the difficulty in making the toxoplasmosis diagnoses, the authors said.

Luft said in an interview this month that "there is extremely strong evidence that all of these patients suffered from AIDS."

About 1,500 cases of AIDS, which destroys the body's immune system, have been reported since the condition was identified in 1979. There is no known cure and about 75 percent of its victims have died within two years. Nine of the 10 patients cited in the *Lancet* article have died, Luft said.

Common AIDS killers include a form of pneumonia and rare cancers such as Kaposi's Sarcoma, in addition to other conditions such as the toxoplasmic encephalitis documented in the *Lancet* article.

AIDS has become widely known as an affliction of homosexuals and drug abusers, but it also is found among heterosexual, non-drug-user Haitians, hemophiliacs, and it has occurred among heterosexual Americans. Many authorities on infectious disease fear that AIDS could spread to the general population. Epidemiologists report that the number of cases is doubling about every six months.

Remington said the study of AIDS could help "lead us to an understanding of infectious agents that can cause cancer. The immune system is the key."

6-13-83 -more-

Most researchers now believe that AIDS is caused by some type of infection that causes the body's immune system to fail by drastically reducing the number of protective T-cells or lymphocytes in the blood. Then a second infection can move in with devastating results, Remington and Luft explained.

They believe that toxoplasmosis is one of those secondary infections. Laboratory studies and analysis of human blood tests have demonstrated that certain infections can disrupt the body's immune system, but no single infection has yet been identified as the trigger of AIDS.

Toxoplasmosis is present in about 50 percent of the U.S. population, Remington said, but the immune system keeps it dormant and under control in most healthy persons. It is spread through undercooked meats, unwashed vegetables, soil and cat feces. Symptoms are usually totally absent or are similar to a mild case of flu, he said.

The ailment usually becomes dangerous only when a woman becomes infected during pregnancy, risking transmission of the disease—and the likelihood of birth defects—on to the unborn child. Toxoplasmosis also becomes dangerous when immunosuppressive drugs are given to persons, such as organ transplant or selected cancer patients.

Luft said the experience at Stanford and Palo Alto Medical Research Foundation has led to the following indications regarding the AIDS-toxoplasmosis link:

- Central nervous system toxoplasmosis can frequently be cured if it is pinpointed and proper drug treatment (with antibiotics) is conducted early. "This is tricky," said Remington, "because cortisone, often used for encephalitis treatment, is not effective and is even harmful when the condition is caused by toxoplasmosis. With the nationwide outbreak of AIDS, it is imperative that physicians be alert to this potential link and the appropriate treatment."

In addition, the symptoms can be quite varied, including such problems as chronic headaches, confusion or seizures. This variability underscores the need for physician alertness and the use of laboratory tests in diagnosis, Remington said.

- Luft said that before the most recent outbreaks, only about 10 cases of toxoplasmic encephalitis in adults had been reported in the past 40 years. (Those cases did not include medically immunosuppressed patients, he said.)

- The 60 patients represent a wide variety of lifestyles, indicating that the AIDS epidemic is not confined to select groups or caused by specific behavior patterns. Among the 10 persons reported in the *Lancet* article, only two had homosexual histories.

"This does *not* mean that the disease has already spread to the general population," said Remington. "What it does mean is that AIDS has the potential to affect a wide variety of persons."

Nevertheless, the link to the homosexual, Haitian, and drug-abuse communities appears valid. One patient described in the article, for example, was not identified with any of the three risk groups but had received a blood transfusion in Haiti following a motor vehicle accident.

- Evidence repeatedly points to the Haitian population as a center of the disease. "It appears," said Luft, "that the disease is endemic in that Caribbean nation. I'm not sure what the significance is except that it is an appropriate area to study the disease and look perhaps for causes—and this is being done."

BAGSHAW NAMED FIRST RECIPIENT OF AVERY CHAIR

STANFORD—

Dr. Malcolm Bagshaw, chairman of the department of radiology and leading authority on the use of radiation therapy for prostatic cancer, has been named the first holder of the Catharine and Howard Avery Professorship.

The Stanford University Board of Trustees approved the new endowed professorship and named Bagshaw the first recipient at its regular meeting Friday (June 10).

Bagshaw, who has served on the Stanford faculty since 1956, has played a key role in developing clinical uses of the medical linear accelerator, which has had worldwide impact on the treatment of cancer. More recently, he has directed clinical studies of hyperthermia, the use of heat to destroy cancerous tumors.

He was also a pioneer in the treatment of localized human cancers with combinations of drugs and radiation, a now common procedure which was experimental only two decades ago.

He has authored or co-authored nearly 150 publications covering broad areas of cancer research and therapy.

Bagshaw has served as director of radiation therapy at Stanford since 1960 and was appointed chairman of the academic department in 1972. A 1950 graduate of Yale University School of Medicine, Bagshaw completed his radiology residency at the University of Michigan School of Medicine in Ann Arbor.

The Catharine and Howard Avery Professorship has been earmarked for a faculty member researching the causes, treatment and cure of cancer, an ailment Mrs. Avery had battled. In 1975 she established a fund for cancer research, which was augmented after her 1981 death to make the establishment of the professorship possible.

Mrs. Avery attended Mills College in Oakland and was a graduate of the University of Washington, Seattle.

Her husband, a resident of Mill Valley, is a 1932 graduate of Stanford.

As a Navy captain during World War II, Avery received several honors, including the Navy Cross, the Legion of Merit, and the Distingusihed Flying Cross. Later he held various command positions, including four years in the NATO headquarters in Paris as representative of the Supreme Allied Cammander-Atlantic.

In 1977, Avery established at Stanford the Douglas P. Avery Band Scholarship in memory of his son, who was killed in an aircraft accident in Munich while attending the University of Maryland, Munich Branch.

CHANGE, IMPROVEMENTS HIGHLIGHTED IN MEDICAL CENTER ANNUAL REPORT

STANFORD—

New construction to modernize Stanford Hospital, a new comprehensive children's medical center, improved clinic services, and a major program in molecular and genetic medicine are part of the "Building for the Future" theme of Stanford University Medical Center's 1983 Annual Report.

"The school, hospital, and clinics are all engaged in new, well-articulated programs," writes vice president for medical affairs Lawrence G. Crowley.

But building for the future is not limited to brick and mortar, he adds. It includes stronger relations with the community, new ties with Children's Hospital, and academic and service-related programs as well as mechanisms for change.

Such mechanisms are essential at a time when external factors are affecting the way academic medical centers will be shaped, organized and managed.

How Stanford Hospital, the faculty practice and the medical school will balance their efforts and the direction they will take are the subject of study by a long-range planning group, Crowley notes. The issues are how to attract and retain the necessary patient populations in the hospital and clinics, "how to maintain our position as a major research center in the basic and clinical sciences, and how to best educate tomorrow's leaders in medicine."

Stanford is completing a $14 million Cardiovascular Research Building, and a $6.5 million modernization program of its outpatient clinics, the base of the faculty's medical practice. It will begin a $125 million modernization of its hospital to serve the needs of patients and their physicians more effectively. The project will be done in phases and construction will begin as soon as state and local agencies approve the plans. They include a new diagnostic and treatment wing, surgical suites and eight new nursing units. Eventually space in the present hospital will be modernized as functions move to the new building.

In addition, the School of Medicine contemplates the development of a major program and building for molecular and genetic medicine, and a center for nuclear magnetic resonance to explore the analytic and diagnostic potential of the technique.

-more-

6-6-83

"Building for the future, however, does not necessarily mean becoming bigger," Crowley cautions. "We hope that our building program will make us more effective, better consolidated, economical to manage. If we can become a more compact, efficient unit I'm convinced that the Center will also become more stimulating intellectually and better positioned to provide medical and scientific leadership for many decades ahead."

The report includes interviews with Dr. Dominick P. Purpura, dean of the school of medicine; Sheldon S. King, executive vice president and director of the hospital; and Donald Tower, executive director of the university clinics and faculty practice program.

All three, according to Crowley, are strong academically-oriented executives who have been here long enough to get a feel of the place and to make plans for their own areas of responsibility.

According to the report, both hospital and Stanford clinics have made major improvements in billing procedures, traditionally problem areas for patients.

The problem wasn't as simple as it seems, however. In the clinics alone, the report notes, it involves 40,000 patient accounts, with 250,000 insurance forms, 300,000 bills to patients, and 2,000,000 individual charges processed annually.

The clinics have also instituted a patient relations program, decentralized and simpler patient registration system and procedures to analyze operating and administrative costs.

The goal, concludes the report, is "making the Stanford clinics competitive with other group practices in terms of service."

Copies of the Annual Report are available from the Office of Medical Development, Stanford University Medical Center, 780 Welch Road, Palo Alto, CA 94304, telephone (415) 497-7305.

HIGH-RISK BABIES AND MOMS: NUTRITIONAL CONSIDERATIONS

Editors, City Desks: Members of the news media are invited to attend and/or cover any portions of this three-day conference.

STANFORD—

A conference on the nutritional care of high-risk obstetrical patients and high-risk infants is being held in Fairchild Auditorium and some M classrooms of Stanford Medical Center today through Friday, June 17.

The conference is oriented to nutritionists, nurses, obstetricians, pharmacists, neonatologists and other physicians who are involved in the care of these patients.

It is intended to increase the knowledge of health care personnel of the nutritional needs of these women during pregnancy and lactation as well as of the immature and ill newborn, and the difficulties encountered in attempting to provide adequate caloric and fluid intake for these infants.

Both theoretical and practical points will be raised through the use of lectures, round tables, and workshops.

Sponsored by the departments of pediatrics, obstetrics and gynecology, and dietetics, the program will include such topics as "New and Future Issues in Perinatal Nutrition," "Severe Preeclampsia: The Highest Risk Pregnancy," "Specific Nutritional Deficiencies and Excesses; Impact on Pregnancy Course and Outcome," "Exercise During Pregnancy," "Ethical Dilemmas in Perinatology," and many more.

The faculty includes many Stanford physicians and other professionals involved with these issues, as well as several knowledgeable guest speakers from around the country. The program directors are Dr. Philip Sunshine, professor of pediatrics and director of newborn nurseries at SUH; and Dr. John Kerner, Jr., director of pediatric gastroenterology.

A fee is charged (*except to members of the news media*), and continuing education credit is available. For further details on the conference and enrollment information, call (415) 497-5711.

EXPERTS CHIDE SOCIETY FOR FAILURE TO NURTURE CREATIVITY IN CHILDREN

STANFORD—

Imbued with the music of a hundred rehearsals, a concert pianist approaches the stage. He has memorized hundreds of thousands of notes, *felt* them at the deepest level of understanding and is ready to touch the soul of the listener with passion, whimsy or pathos. As he touches the keys, the audience and the concert hall disappear from his consciousness. He becomes the music, and the music plays itself, pulsing, undulating to a rhythm that swells from within.

Then the block comes.

"The performer makes some type of mistake, often undetectable, sometimes inaudible," said Lorin Hollander. "At times he can take it in stride and go on as though nothing has happened. But other times, panic sets in." The critical judge, the mythical listener who is all knowing and all powerful, arises from the performer's powerful imagination, blocking any further creativity.

Such blocks to creativity can arise and be just as destructive to "performers" in any field, said Hollander, who suffered his first block of stagefright at age eleven, when he played his first concert at Carnegie Hall. At a meeting of Stanford Medical School alumni Saturday (June 4), Hollander shared the stage with Nobel laureates David H. Hubel and Joshua Lederberg as the three peeled apart the anatomy of creativity.

Though their fields are disparate—Hubel a neurobiologist, Lederberg a geneticist, and Hollander a concert pianist—all are teachers, eager to identify the roots of creativity so that they can nurture it in their students.

"We have a problem," Hollander said. "We are not nurturing creativity in children. Indeed, it seems that in our educational system, the creative process of children is being destroyed."

"I think boredom is important," Hubel said. "Giving students a chance to get bored enough to think up problems may be critical. If there's one thing important to creativity, it's being saturated in a problem most of the time, most of the day," said Hubel. He pleaded for letting creative people immerse themselves in uninterrupted time to think. Creativity needn't decline as one gets older, Hubel suggested, "but it takes a certain amount of stubbornness against the outside world."

In the years since his Nobel award winning work deciphering the genetic tricks of bacteria, Lederberg, who left Stanford in 1977 to become president of Rockefeller University, has spent part of his time researching the biographies of scientific discoveries and the people who make them.

-more-

6-6-83

The work has been "interesting, but not enlightening," Lederberg said. Even keeping detailed lab notebooks of his own group's work, in hopes of chronicling the leaps of creative insight that marked a major reversal in a theory or dogma, proved unfruitful.

"In a few moments of discourse, the whole frame of discussion changed so much that we couldn't write it down five minutes later," he said.

Lederberg cited a question taken from a college entrance exam as the kind of trap that trips up the creative student. Though the test givers were seeking a single "obvious" definition for the word "nucleotide," any student who looked a layer deeper into the definition could have realized that all of the options given might be considered correct.

"I suggest that we have a world full of special traps like this for the special and creative student," Lederberg said. "There's a penalty for thinking."

Instead, Lederberg cited his own experience as a 22 year-old graduate student as an ideal form of learning.

After two years of medical school, Lederberg did graduate work at Yale University that challenged the age-old dogma that bacteria have a very limited genetic make-up, and reproduce simply by dividing—without the help of a mate.

By mixing two different colored strains of bacteria together and growing the hybrids in a culture], Lederberg made a radical discovery.

Months later, he found himself at a gathering of expert geneticists, where he could meet each criticism and challenge to his theory head on, without waiting for the delays of debate in the medical literature.

"Imagine a 22 year-old coming up and saying, 'look you guys, you haven't been noticing all these years—bacteria do have sex!' "

Such a willingness to challenge dogma, though necessary to creative solutions, is easily squelched in today's elite universities, he said.

"Our institutions today probably do a very good job as filters, making sure that we get the best and the brightest students. But I'm not so sure that we do a very good job as nurturers."

Hollander cited a Moslem mystic who wrote, "Look not for the devil in the desert, but in the over-critical teacher." Early criticism is often internalized and projected back much bigger than life, he said. Like a snail in its shell, a child withdraws at early criticism and the scars can remain into adulthood.

Far from eliminating grades and criticism, Hubel and Lederberg—who admitted to earning "poor C's" in some graduate courses—agreed that criticism should be fair and tempered with praise.

"We don't want to eliminate the game, but let the child see what the game is," said Hollander. "Life gives grades, but let's let the kids learn the relative importance of grades."

An education in the arts can permit the freedom of expression, said Hollander, that can help an adult or child face down the critic within himself, to permit creativity to bud and flower.

GLOOMY PREDICTIONS FOR ACADEMIC MEDICAL CENTERS

STANFORD—

Academic medical centers are going to get smaller and their hospitals less socially relevant in terms of the poor and inner-city needs, Dr. David E. Rogers, president of the Robert Wood Johnson Foundation, predicted here Saturday.

University hospitals, in an effort to survive, will examine services that produce deficits and try to eliminate them, and expand those services that pay well, Rogers predicted.

He cited a recent Urban Institute analysis suggesting that the first to get the ax will be services for the poor—among them home care, family planning, rehabilitation and social services. Next on the hit list would be burn care units, neonatal intensive care units, and outpatient departments with community orientation.

Such cutbacks would affect the poor severely, he added, because although academic medical centers and their hospitals make up only 5.6 percent of the nation's hospitals, they deliver a disproportionate share of 47.2 percent of charity care.

Rogers discussed the gloomy future as well as the challenges facing academic medical centers at the annual meeting of the Stanford Medical Alumni Association. The Princeton, New Jersey based Robert Wood Johnson Foundation is one of the largest in the nation, interested in improving health care in the United States.

"We will see progressive shrinkage in the size of basic science departments and top heavy clinical faculties," Rogers said. Faculty clinicians will be recruited largely for their abilities to attract patients with problems which result in high fees and good hospital reimbursement rather than teaching or research skills.

6-6-83

-more-

While 20 to 30 major academic medical centers, including Stanford, will be able to continue—even expand—their biomedical research capabilities, Rogers said, most others will shrink progressively. The latter will become increasingly training institutions for doctors, more reminiscent of pre-Flexnerian days, with less and less resemblance to other university graduate programs, and more tenuous university ties.

"It seems to me clearly evident that the nation is at present unwilling to pay the full costs of all the research," he said.

In addition, because of the oversupply of physicians and the high costs of care created in part by high technology and overspecialization—government at all levels, and the public, will demonstrate a progressive unwillingness to pay all of the costs to sustain those features which distinguish the academic medical center like medical education, residency training, research and scholarly pursuits.

"In an effort to stay afloat, many academic medical centers will begin to expand all high technology areas—open heart surgery units, pathology laboratories, intensive care units, CT scanners and radiotherapy units," he said. "These generate respectable revenues.

"They will create or spin off or unbundle potential profit-making enterprises, or establish satellite clinics or affiliations with smaller hospitals and HMOs and other health delivery plans to ensure an adequate flow of patients. They may get involved in the construction of facilities for fee-for-service ambulatory care, preventive health services, or health spas.

"Faculty and hospital board meetings will increasingly resemble the annual stockholder meetings of multi-national corporations."

Rogers said "it would be a dreadful mistake if academic medical centers became just another profit-making institution."

"The most compelling long-term justification for their existence lies in their championing of certain values," he said. "Like the churches, they have been at their best when they have served as important, powerful spokesmen for good science and the humanistic values which characterize a caring responsible society."

Until happier days return, Rogers suggested that academic medical centers should turn the spotlight on their unique social purpose—the training of young men and women to be the doctors of tomorrow.

-more-

"In the rush for bigness, medical students have almost been forgotten," he said. "More attention to the care and feeding of medical students should be given, more rewards to faculty for paying attention to them, more concern for their attitudes toward science, for the values they acquire, and the ways they approach the care of the sick.

"Despite the costs, academic centers should stoutly maintain their traditional mission of caring for the less fortunate. Over time this will compel public support.

"If academic centers abandon this mission, I'm afraid they will become simply another indistinguishable part of our profit oriented society and the medical profession, the doctors we turn out, and society, will be the poorer for it."

"Reestablish the commitment to make the health professions in general mirror the social, racial and cultural makeup of our society," Rogers admonished. "We made a good start but we are faltering."

Rogers said academic centers should also seriously address the problem of the oversupply of tertiary care oriented superspecialists.

These young, elegantly-trained superspecialists are populating well-financed suburban hospitals and taking paying patients away, he said. Academic centers are now far less referral institutions than in times past.

"It is killing you," he told the audience. "The crying need is for more generalist physicians."

STANFORD UNIVERSITY BLOOD CENTER TO SCREEN ALL DONATIONS FOR AIDS

STANFORD—

All blood donated to the Stanford University Blood Center will be screened starting July 1 for an abnormality frequently associated with AIDS, the center's medical director said Friday (June 3).

AIDS, short for Acquired Immune Deficiency Syndrome, is a deadly family of immune disorders whose elimination was billed last week as the "No. 1 priority" of the U.S. Public Health Service.

Edgar Engleman, assistant professor of pathology and medicine and medical director of the Blood Center, said the screening test was made possible by equipment and high technology already used in research at the center, and will raise the cost of each blood product by only $6 to a total of up to $64.50.

Based on a pilot study of 200 patients, Engleman estimates that between 1 and 2 percent of Stanford's 18,000 blood donors will be excluded on the basis of the screening. Not all the donors thus excluded have AIDS, Engleman emphasized. In fact,the majority may be completely healthy, because the screening method is not perfect. "But it's the best method available," he said.

Although several methods of screening blood have been discussed nationally, none—so far—have been selective enough to screen out only those donors with AIDS.

"Most of the proposed screening methods would eliminate between 15 and 50 percent of the donors, and only a tiny fraction of those actually have AIDS," Engleman said. "Blood is such a precious resource that we need to be fairly certain that our screening process is highly selective to make screening worthwhile."

Engleman said the testing was begun as a precaution, not because there have been any known cases of AIDS in Stanford blood recipients. The Blood Center already has begun other precautions, such as asking potential donors from groups at high risk for contracting AIDS not to donate blood. Such high risk groups include homosexual men who are active with multiple partners, intravenous drug abusers and Haitian immigrants.

6-3-83

-more-

The test Stanford will use examines infection-fighting white blood cells called "T-cells" that drop to abnormally low concentrations in the blood of about 95 percent of all AIDS victims. Such patients also experience a dramatic change in the ratio of two subgroups of the cells called "helper T-cells" and "suppressor T-cells." Healthy donors have more helper T-cells than suppressor cells but, for an unknown reason, that ratio is reversed in AIDS patients, Engleman said.

Using monoclonal antibodies—specially manufactured proteins— and a space-age research tool called a fluorescence activated cell sorter (FACS), Engleman and his colleagues can detect the subtle clues in the blood of donors who may have contracted AIDS without realizing it.

The technique has been used in the past to confirm AIDS diagnosis, but its cost of between $150 and $200 per test made it impractical as a screening tool. By simplifying the test and increasing the volume of tests in each batch, Stanford can reduce the cost to the $6 level, he said.

Although the technology is available to other blood banks, few have the equipment or expertise to make their own monoclonal antibodies, said Engleman, who sees Stanford's upcoming screening program as an interim tool to be used until researchers can develop a simpler and cheaper test that is just as effective.

"As soon as a better test comes along, we'll be willing to use it," he said. "In the meantime we're using existing technology to try to prevent the spread of AIDS."

SHUMWAY, KREVANS AND HEART PATIENTS STRESS IMPORTANCE OF ANIMAL RESEARCH

STANFORD—

Patients who have benefited from animal research called on California lawmakers Monday to defeat proposed legislation that would bar scientists from using abandoned animals sold to laboratories by shelters and pounds.

The bill, SB 883, pushed in Sacramento by an increasingly powerful lobby, has been passed by the senate, and is scheduled for a hearing before the Assembly Committee on Government Operations August 17.

The patients were joined by scientists and officials from Stanford and the University of California Medical Center in San Francisco at a press conference held on the UCSF campus.

"Senate Bill 883 must be opposed," said Stanford heart transplant patient Bill Boxberger.

Boxberger, 39, of Madera, California, has suffered from a lifelong heart condition. "My whole life is like a history of research." said Boxberger. He pointed to a young patient seated nearby who received his latest heart surgery last Wednesday.

"When I was that age, these procedures just didn't exist," said Boxberger, referring to Albert Lamb, 12, Modesto, California, who sat in a wheelchair beside his father, Albert Sr.

Julius R. Krevans, M.D., chancellor of UC—San Francisco, said the purpose of the joint conference was "to share with you some of our understanding of why this (animal research) is important, and why some of the legislative issues which are underway at the present time are, potentially, extraordinarily disruptive."

Krevans sat beside Norman E. Shumway, M.D., chairman of Stanford's cardiovascular surgery department, who emphasized that SB 883 would seriously impede medical research in California. The proposed law would prohibit the use of pound animals in California, and the importation of pound animals from other states after 1986. The bill is sponsored by Senate President Pro Tem David Roberti, (D—Hollywood).

"For reasons that are difficult to understand, it (SB 883) has gained momentum," Shumway said. He attributed the bill's apparent momentum to the "pleas of Hollywood persons who know nothing about research." Shumway said that the acquisition of vast amounts of knowledge will continue to require the use of pound animals. He pointed specifically to the search for new and improved heart valves, and better anti-rejection drugs for use by transplant patients.

7-25-83 -more-

"There are so many avenues ahead of us, it is ridiculous to say that we have researched to some level of perfection and now we can just stop," Shumway said. In Britain and other European countries, where animal legislation is much tougher than in California, there have been "no significant advances," in research in cardiovascular surgery in these otherwise highly sophisticated nations, he said.
